THE CELEBRATED XL ALL SPECIALITIES. BEEN ON TOP FOR 25 YEARS AND STILL THERE!—XL ALL CAUSTIC WINTER WASH (in powder). 1lb. tin makes 8 to 12 gallons. It thoroughly cleanses Fruit Trees and Bushes, both buds and bark. Can be used any time before the buds begin to swell in the spring. XL ALL NICOTINE LIQUID INSECTICIDE. The gardeners' favourite Wash for the absolute destruction of Thrip, Scale, Mealy Bug, &c. If this wash is used occasionally, a total absence of insects, both on Fruit Trees and Plants, can be secured in any garden. XL ALL NICOTINE SHREDS. The most potent, safe, and effectual Fumigant. Used without any apparatus, simply burn on the floor of the Greenhouse. XL NICOTINE FUMIGATING COMPOUND. Both in liquid and cake, these old favourites are still as popular as ever. Many other XL ALL Preparations are indispensable in the garden. Get a complete list from your N.S. or Florist, or send to me for one and name address of your nearest Agent.—G. H. RICHARDS, Manufacturer, 234, Borough High Street, London, S.E. 1.

NOTICES.

FOR SALE at

RUDGWICK FRUIT FARM, Rudgwick, Sussex, surplus stock of about 1,500 four-year well-grown Cordon Apple Fruiting Trees, on Paradise Stock, of the following varieties:—

"ALLINGTON PIPPIN."
"JAMES GRIEVE."
"LANE'S PRINCE ALBERT."
"NEWTON WONDER."
"WELLINGTON."
"BRAMLEYS."
"RIVAL."

Also a number of Pyramid and Bush Lady Sudeley, fine fruiting trees, 7 years, and a few hundred of Boskcop Giant Black Currant Stools, suitable for Market Gardens.

Some Cox's O. P. Cordons.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY, established in 1865, has invested funds amounting to £54,800. It assists members during Sickness, Convalescence, and Distress, and enables them to make some provision for old age. All Gardeners are invited to join the Society. Lads over 12 years of age are admitted to the Juvenile Branch.—Full particulars from A. C. HILL, Secretary, 35, Alexandra Road, West Kensington Park, W. 14.

PLANTS, &c., WANTED.

WANTED, 1,000 large ASPIDISTRAS, old plants, suitable for stock; cash or exchange. See other advertisements; catalogues free. — SMITH, London Fern Nursery, Loughborough Junction, London, S.W. 9.

WANTED, White and other Currant Cuttings; also rooted plants, Gooseberries. Cobnuts and Filberts, suckers or transplanted for stock; Dwarf Bush Roses—"NURSERYMAN," Box 22, 41, Wellington Street, Covent Garden, W.C. 2.

WANTED, Strawberry Plants, in large pots, ready for forcing. — State name of Strawberry, also price, to GARDENER, A. Stanley Garton, Esq., Wood Lodge, Burgh Heath, Tadworth, Surrey.

WANTED, for a small holding, Narcissus Tulips, any sort of bulbs, Fruit Trees, also Curnarts, Gooseberries, Strawberries, Fowls, Ducks, Geese. —Description and price to WESTON, Manor Farm, Wolvercote, Oxford.

PLANTS, &c., FOR SALE.

SPECIAL OFFER.

FOR IMMEDIATE DISPOSAL.

A LARGE TRADE STOCK of ESTABLISHED ORCHIDS, comprising

50 ONCIDIUM ROGERSII, 30s. per dozen.
50 DENDROBIUM WARDIANUM GIGANTEUM, good plants, showing bud, 60s. per dozen.
100 ODONTOGLOSSUM GRANDE, smart plants, in two sizes, 30s. and 60s. per dozen.
300 CATTLEYA GASKELLIANA, fine plants, in 6in. pots, 2 and 3 leads each, 60s. per dozen.
300 CATTLEYA and LAELIO-CATTLEYAS, HYBRIDS, good plants and useful decorative varieties, in 6in. pots, 48s. per dozen.
500 CATTLEYA and LAELIO-CATTLEYA SEEDLINGS (unflowered), of very choice parentage, purchased from the "Brackenhurst" collection, nice sound plants, mostly in 2in. pots, 20s. per dozen.
2,000 ODONTOGLOSSUM CRISPUM, smart plants, in 4in. and 5in. pots, £12 per 100.
2,000 ODONTOGLOSSUM CRISPUM, nice plants, in 3in. pots, £6 per 100.
5,000 ODONTOGLOSSUM CRISPUM, small plants, healthy and sound, many unflowered, 50s. per 100.

These Od. Crispum are the best type, the famous and beautiful Od. Crispum "Solum," and Od. Crispum "Queen Empress," and others having originated from this stock.

The above is a specially cheap offer, as the plants must be cleared immediately, thus affording a most favourable opportunity to buyers desirous of replenishing stocks, as no importations from abroad are likely to arrive for some time.

Specially favourable terms to large buyers.

Full particulars from and all inquiries to A. J. KEELING & SONS, Westgate Hill, Bradford.

ELSOM'S PEAS. — Peas being scarce should be bought immediately. Pilot, 3ft., 1s. 10d.; Gradus, 3ft., 1s. 10d.; Elsom's Early Gem, 18in., 2s. 4d.; Little Marvel, 2ft., 2s. 4d.; all per pint; postage, 1 to 3 pints 6d. extra.

ELSOM'S BROAD BEANS.—Early Long Pod, 7d.; Exhibition Long Pod, 10d.; Green Windsor, 8d.; Giant Windsor, 9d.; all per pint; postage, 1 to 3 pints, 6d. extra.

ELSOM'S ONION SEED.—For monster Onions sow early in the year. Bedfordshire Champion, Giant Zittau, James' Keeping, Rousham Park, Nuneham Park, all 1s. 3d. per oz.; Ailsa Craig, 2s. 3d. per oz.; post free.

ELSOM'S SELECTED SEED POTATOS. —Duke of York, 4s. 6d.; Early Victor, Express, Ashleaf, 4s.; carriage paid and bags free.

ELSOM'S TOMATOS, for early sowing.— Fillbasket produces heavy trusses of the nice medium-size fruit so much in request. Ailsa Craig, for earliness, quality, and cropping power this Tomato is unrivalled. Both these varieties are suitable for growing in or out of doors. Seed of either (raiser's stocks), 25 6d., 100 1s. 6d.; 250 seeds, 2s. 6d., post free. Elsom's seeds are all guaranteed of standard germination and purity.

ELSOM'S special terms to Allotment Secretaries and Seed Agents sent post free on application.

GEORGE ELSOM, Seed Merchant, Spalding, Lincs.

AMARYLLIS. — 6 doz. Veitch's and Keer's Hybrids, some bulbs 10in. in circumference. £1 per dozen, or £5 10s. the lot.—GARDENER, Oak Cottage, Chobham Road, Frimley, Surrey.

FERNS! FERNS!!—Tree Ferns, Climbing Ferns, Basket Ferns, Stove and Greenhouse Ferns, Hardy Garden Ferns; catalogues free. — J. E. SMITH, London Fern Nursery, Loughborough Junction, London, S.W. 9.

TWO large Imantophyllum Miniata Clivia, in 14in. pots; 25s. each. — GARDENER, Frimley Warren, Surrey.

SCOTCH SEEDS, Perfection, East Lothian Stocks, Crimson, Purple, Scarlet, White, Pink, Gold Striped French Marigolds, African Lemon and Orange, Scotch Fancy Pansies, Violas, mixed, &c.— TILLIE, WHYTE & CO., 12, Melbourne Place, Edinburgh.

ENGLISH YEWS.—The cleanest and healthiest lot in England; every plant a perfect specimen and splendidly rooted; 2ft. to 2½ft., 60s. per 100; 2½ft. to 3ft., 90s. per 100; 3ft. to 3½ft., 120s. per 100; 3½ft. to 4ft., 150s. per 100; 4ft. to 4½ft., 24s. per doz.; 5ft., 30s. per doz.—HINTON BROS., LTD., The Warwick Nurseries, Warwick.

SCOTCH SEED POTATOS, Duke of York, Midlothian Early, Epicure, Sharpe's Express, Edzell Blue, Early Pioneers, Majestic, &c. List free.— TILLIE, WHYTE & CO., 12 Melbourne Place, George IV. Bridge, Edinburgh.

100,000 LARGE GARDEN FERNS, 20s. 100; Palms, Begonias, Crotons, Dracaenas, Roses, Ericas, Gloxinias, Lilies, Hydrangeas, &c.; catalogues free.—J. E. SMITH, London Fern Nurseries, Loughborough Junction, London, S.W. 9.

MISCELLANEOUS.

THEY NEVER FAIL TO KEEP YOU DRY.

If you write to-day for the "Beacon Booklet," you are on the way to weather comfort. It shows many different styles in BEACON OILSKINS, and it will show you the coat that you want. Children's Coats 16s. 6d. upwards, Men's from 25s., Ladies' Smart Oilskins, 28s. 6d. Long Leggings from 5s. Sou'-westers from 3s. They always keep out the wet. Send p.c. to-day for our Free Booklet of "Weather Comfort," describing money-back guarantee.—Send now—before you forget—to BARBOURS, LTD., 66, BEACON BUILDINGS, SOUTH SHIELDS. (4)

A TIME SAVING BOON A Unique Green Clouding, mixed and removed with simply cold water. Last whole season. Try it. Include in next seed order, a Sample of Elliott's New "Pingo" Summer Shading, Pkts. 1/6 or 7lb. bag 15/6, carr. paid, of Maker F. ELLIOTT, Alfred Road, London, W. 3.

GLASSHOUSES for sale; also Garden Lights, Glass, Boilers, Pipes, Fittings, Standpipe Valves Hose, &c.; price against specification.— C. A. CHRISTIANSEN, Southall.

"PESTITE" kills wireworms, rookworms, cockchafer grubs, Julus worms, and other soil pests; also "club root" and other fungoid diseases. Price: 28lbs. 5s. 6d., 56lbs. 7s. 6d., 112lbs. 10. 6d., 1 ton £8, all carriage paid, from G. LANG & SONS, LTD., Hounslow, Middlesex.

ENGLISH YEWS.—The cleanest and healthiest lot in England; every plant a perfect specimen and splendidly rooted. 3ft. to 3½ft., 120s. per 100; 3½ft. to 4ft., 150s. per 100; 4ft. to 4½ft., 24s. per doz.; 5ft., 30s. per doz.

HINTON BROS., LTD., The Warwick Nurseries, Warwick.

PRIVET, large oval leaf, 2½ to 3 feet, 10s. per 100; 3 to 4 feet, 15s. per 100.—HINTON BROS., Warwick Nurseries Warwick.

ENGLISH OAKS, the finest stock in England, 5 to 7 feet, 50s. per 100.—HINTON BROS., Nurserymen, Warwick.

LIMES, true red twigged, 8 to 12 feet, beautiful trees, 12s. per dozen; larger sizes to offer.—HINTON BROS., Nurserymen, Warwick.

SCARLET OAKS, grand colour, 5 to 7 feet, 60s. per 100.—HINTON BROS., Nurserymen, &c., Warwick.

WEEDS! WEEDS! WEEDS! Now is the time to destroy them before casting their seeds. If your paths are cleared now they will remain clean for the best part of next year. Our Weed Killer is safe to handle, non-poisonous, will not harm birds or animals, is a powder; only requires sprinkling on the weeds.

"BLUE" ORCHIDS.

TO respond literally to an invitation to write on "Blue Orchids" would be a simple task, for I know of no truly Blue Orchid save the lovely Vanda coerulea, and even this seems so self-conscious of its solitary isolation or fearful of being thought a freak, that its colour is but fleeting, possibly even artificial. A new species may yet be discovered to surprise the Orchid world and help the hybridist; or, to the marvels of hybridisation already accomplished, a cross may be added between this beautiful Vanda and some other species, resulting in a series of genuinely blue Orchids. But if Vanda coerulea is the only "blue" amongst Orchids, it is a truly magnificent representative, admired by all. Some regard as blue the pretty Dendrobium Victoria Regina, but it requires the imagination of Shakespeare, who wrote of "Daisies pied and Violets blue," or of the author of "The Rose is red, the Violet blue."

But, no doubt, I am expected to include the more nebulous forms usually designated "coerulea" or "coerulescens." To attempt to arouse amongst the fraternity of Orchid experts appreciative enthusiasm of these would be a hopeless task—about as easy as to enthuse an active-service hero by an article upon the merits of the non-combatant corps, with special reference to the Conscientious Objector! These so-called Blue Orchids are not in fashion. The expert fixes a standard which includes size, substance and, with the exception of the albino, strong, striking, or gorgeous colourings—just the qualities which the "blues" lack. Nevertheless if, as a consequence of arbitrary fashion, they are not allowed their place in the sun, and find themselves unable to live amongst their giant and coloured relatives, their flowers are unique and delicate, and they produce most beautiful effects in floral decoration. One of my Orchid houses, in which were arranged numerous flowering varieties of the type last November, proved a revelation to some of my Orchid friends. Still, I am under no misconception as to the Orchid world's estimate of these coerulean types, and when Orchid groups have to be submitted to the judgment of the expert it is prudent to leave one's Blue Orchids in lone glory at home. But they have their friends and admirers amongst lovers of flowers, if not amongst lovers of Orchids, as I have proved by the test of an occasional group at Vincent Square. However, let no one introduce Blue Orchids into their gardens in the fond hope that they will bring fame or fortune. Their very name invites disappointment, although appropriate enough if we remember that skies are as often leaden or silvery as blue. Perhaps "heavenly" was intended by the designation coerulean. They must be numbered amongst the many beauties in nature which are lovable for their modesty: subdued and delicate in colour and graceful in pose, they are essentially flowers for those of aesthetic and refined tastes, who find joy and rest in the contemplation of the unobtrusive. Perhaps it is on the principle of homoeopathy that the atmosphere of the Blue Orchid can be prescribed as a cure for a fit of the "blues."

To the hybridist Blue Orchids are of distinct interest. Crossed together, the resulting hybrids usually come true to colour. I have raised in quantities Cattleya Portia coerulea (Bowringiana violacea × labiata coerulea), C. Ariel coerulea (Bowringiana lilacina × Gaskelliana coerulescens), and C. Alcimeda coerulea (labiata coerulea × Gaskelliana coerulescens), with the usual variation in shape and size, but little variation in colour. But, as might be expected, when

FIG. 1.—CATTLEYA BOWRINGIANA LILACINA.

crossed with coloured varieties they lose their individuality of colour, e.g., I have raised C. labiata Amesiana crossed with C. labiata coerulea, and the resulting hybrid, although coerulean to a degree, evidences a warmth foreign to the true coerulean type. In other ways they are proving good parents. C. Blanche, raised in my collection between C. labiata coerulea and C. maxima gigantea, although it has completely lost all trace of coerulean tint, has acquired a beauty of shape and refinement which makes it highly attractive. I have recently seen a C. Blanche raised by an Orchid friend from a C. labiata of the recognised type, which gives a flower of fine size and substance at the expense of beauty. But Brasso-Laelio-Cattleya Antoinette (C. Portia coerulea × B.-L. Helen), raised in my collection, which recently secured the R.H.S. First-class Certificate and was illustrated in *Gard. Chron.*, December 7, 1918, provides an agreeable surprise. Unique in comparative size of lip and petals, the result is remarkable and unexpected, the bright, rosy-mauve colour giving at a glance no suspicion of "blue," but a close inspection suggests that under the surface-colour is a ground of blue, which may account for its superior richness of colour. A further peculiarity is the almost complete disappearance of Brassavola. If hybridists attempt to rival this novelty they should not forget that the C. Bowringiana parent of the C. Portia used is distinct and fine, but the result achieved would suggest that when the finer C. Ariel coeruleas are used, we may look for a series of desirable hybrids with broad petals and open lips, although there seems no reason why the ordinary reds should not produce equally good results, provided the parents are well chosen and similarly shaped. What may result from crossing the "blues" with yellows and whites has not yet been satisfactorily proved. One would not be sanguine of avoiding a muddy colour.

Just as there are albino forms of most species, so blue types are by no means rare. In my collection I have three quite distinct blue forms of C. Bowringiana (one of these is illustrated in fig. 1), differing from each other in size, colour and shape. In many species the blue appears only as a blotch on the lip, or merely a pencilling in the throat. Every Orchid grower will be familiar with various blue forms of C. Mossiae, C. Mendelii, C. Trianae, C. labiata, and Laelia pumila. As with the albinos, these varietal forms often prove difficult subjects in cultivation, following the law of nature, which creates the delicate and refined more wayward than the robust. No comprehensive list of blue Orchids can be given, with the uncertainty of what to include and what to exclude. For instance, should the pretty and floriferous Odontoglossum Edwardii be included? It is as blue as a Violet and as many other Orchids designated blue. Many of the Odontoglossums, too, have a suspicion of blue. But amongst the so-called blue which occur to me, besides those already mentioned, are: Vanda coerulescens, Bollea coelestis, Rhyncostylis coelestis, Aspasia odorata, Galeandra devoniana, Calanthe Masuca, Schlimmia trifida, and Miltonia Phalaenopsis. So far as my collection is concerned, we treasure a Cattleya Trianae with a very dark lip, Dendrobium Phalaenopsis Schröderiana Gatton Park var., Laelia pumila Gatton Park var., and the very lovely Cattleya Mendelii Lady Colman.

I have endeavoured to write something interesting, something practical, and something historic. For beauty and refinement the Blue

Orchids have no superiors. Certain of the types are so floriferous and easy to grow that they would prove a valuable acquisition to those who supply florists' flowers. Were these coerulean types procurable, the florist would find them invaluable, as, in combination with suitable flowers and foliage, novel and varied effects could be produced in bouquets and decoration which would never fail to harmonise with their surroundings, as is too frequently the case where rich colours are introduced. *Jeremiah Colman (Chairman of the R.H.S. Orchid Committee), Gatton Park, Surrey.*

THE ROSARY.

A NEW DISCOVERY CONCERNING BLACK SPOT DISEASE.

My recent article on the control of Rose diseases has produced a crop of correspondence which seems to show that disease was particularly prevalent in 1918 in many gardens. None of my letters, however, has proved more interesting than one I received from Mr. N. L. Alcock, of Kew, who has very kindly forwarded to me a paper which he contributed to the *Kew Bulletin* (No. 6, 1918) on the life-history of the Rose Blotch Fungus, which is known to most of us as Black Spot.

Many rosarians have endeavoured to ascertain how the fungus of this disease lives through the winter, in order that steps may be taken to destroy it before it begins its baleful work in the following summer. The view most commonly accepted is that the spores of the disease which appear on the leaves fall to the ground with them and are left dormant in the soil until the warm weather of the next summer wakes them to life, and on this hypothesis attempts have from time to time been made, not, I think, wholly without success, to get rid of the disease either by wholesale removal of the top 3 inches of soil; by sterilising it mechanically, or by burying it deeply below the surface. The collection and burning of all diseased leaves has also been frequently recommended.

Mr. Alcock throws some doubt on the effectiveness of these methods. At the same time he finds that infected leaves which had remained green throughout the winter may preserve abundant spores of the disease, and he therefore considers that the collection and burning of these green leaves constitutes a valuable measure for controlling the disease.

He has, however, made an important discovery in the life-history of the fungus.

When pruning Roses in the spring patches of discoloured tissue were noticed on the young wood of the previous season, apparently caused by some fungus. On examination these were found to contain abundant mycelium and compact masses of fungus tissue bearing spores of Actinonema rosae (i.e., Black Spot).

The infected parts present a blackened, blistered appearance, dotted wih pustules; the mycelium was itself colourless and was confined to the cortex, where it developed considerably and killed the tissues. In spring the mycelium gives rise to conidiophores, which bear spores precisely similar to those formed on the leaves. Mr. Alcock considers that his discovery of the winter stage of the disease on the wood necessitates a modification in the methods of controlling the disease, and that something may be done by careful pruning. He points out that the requirements of different groups of Roses will have to be studied, in addition to the necessity of removing all affected wood.

So far as he has observed, the old pustules on the two-year-old wood become effete and do not bear spores. It follows, therefore, that attention need only be concentrated on the wood of the previous season. He warns us also to remember that it is not all brown specks and spots on Rose-wood that are caused by Actinonema (Black Spot), and suggests that in case of doubt they should be examined under the microscope.

Moreover, he wisely recognises that in spite of careful pruning some pustules on affected trees are almost certain to escape detection, and, further, that spores might be brought by the wind from neighbouring gardens. It is therefore important not to omit spraying or dusting with fungicide and to begin doing this early, to prevent the fungus obtaining entry into the leaves, as when once this has been effected the mycelium continues to grow between the tissues and the blotches inevitably follow.

Mr. Alcock's discovery of the winter stage of the disease is undoubtedly of considerable interest and importance to Rose growers, and if it should turn out to be the case that this is the chief or sole method of the preservation of the fungus from one season to another it should be of great assistance towards enabling us to free our gardens from this troublesome pest, which is so fatal to our autumn Roses. But most of us have discovered that there is no royal road to success in Rose-growing that will supplant unremitting attention and observation. *White Rose.*

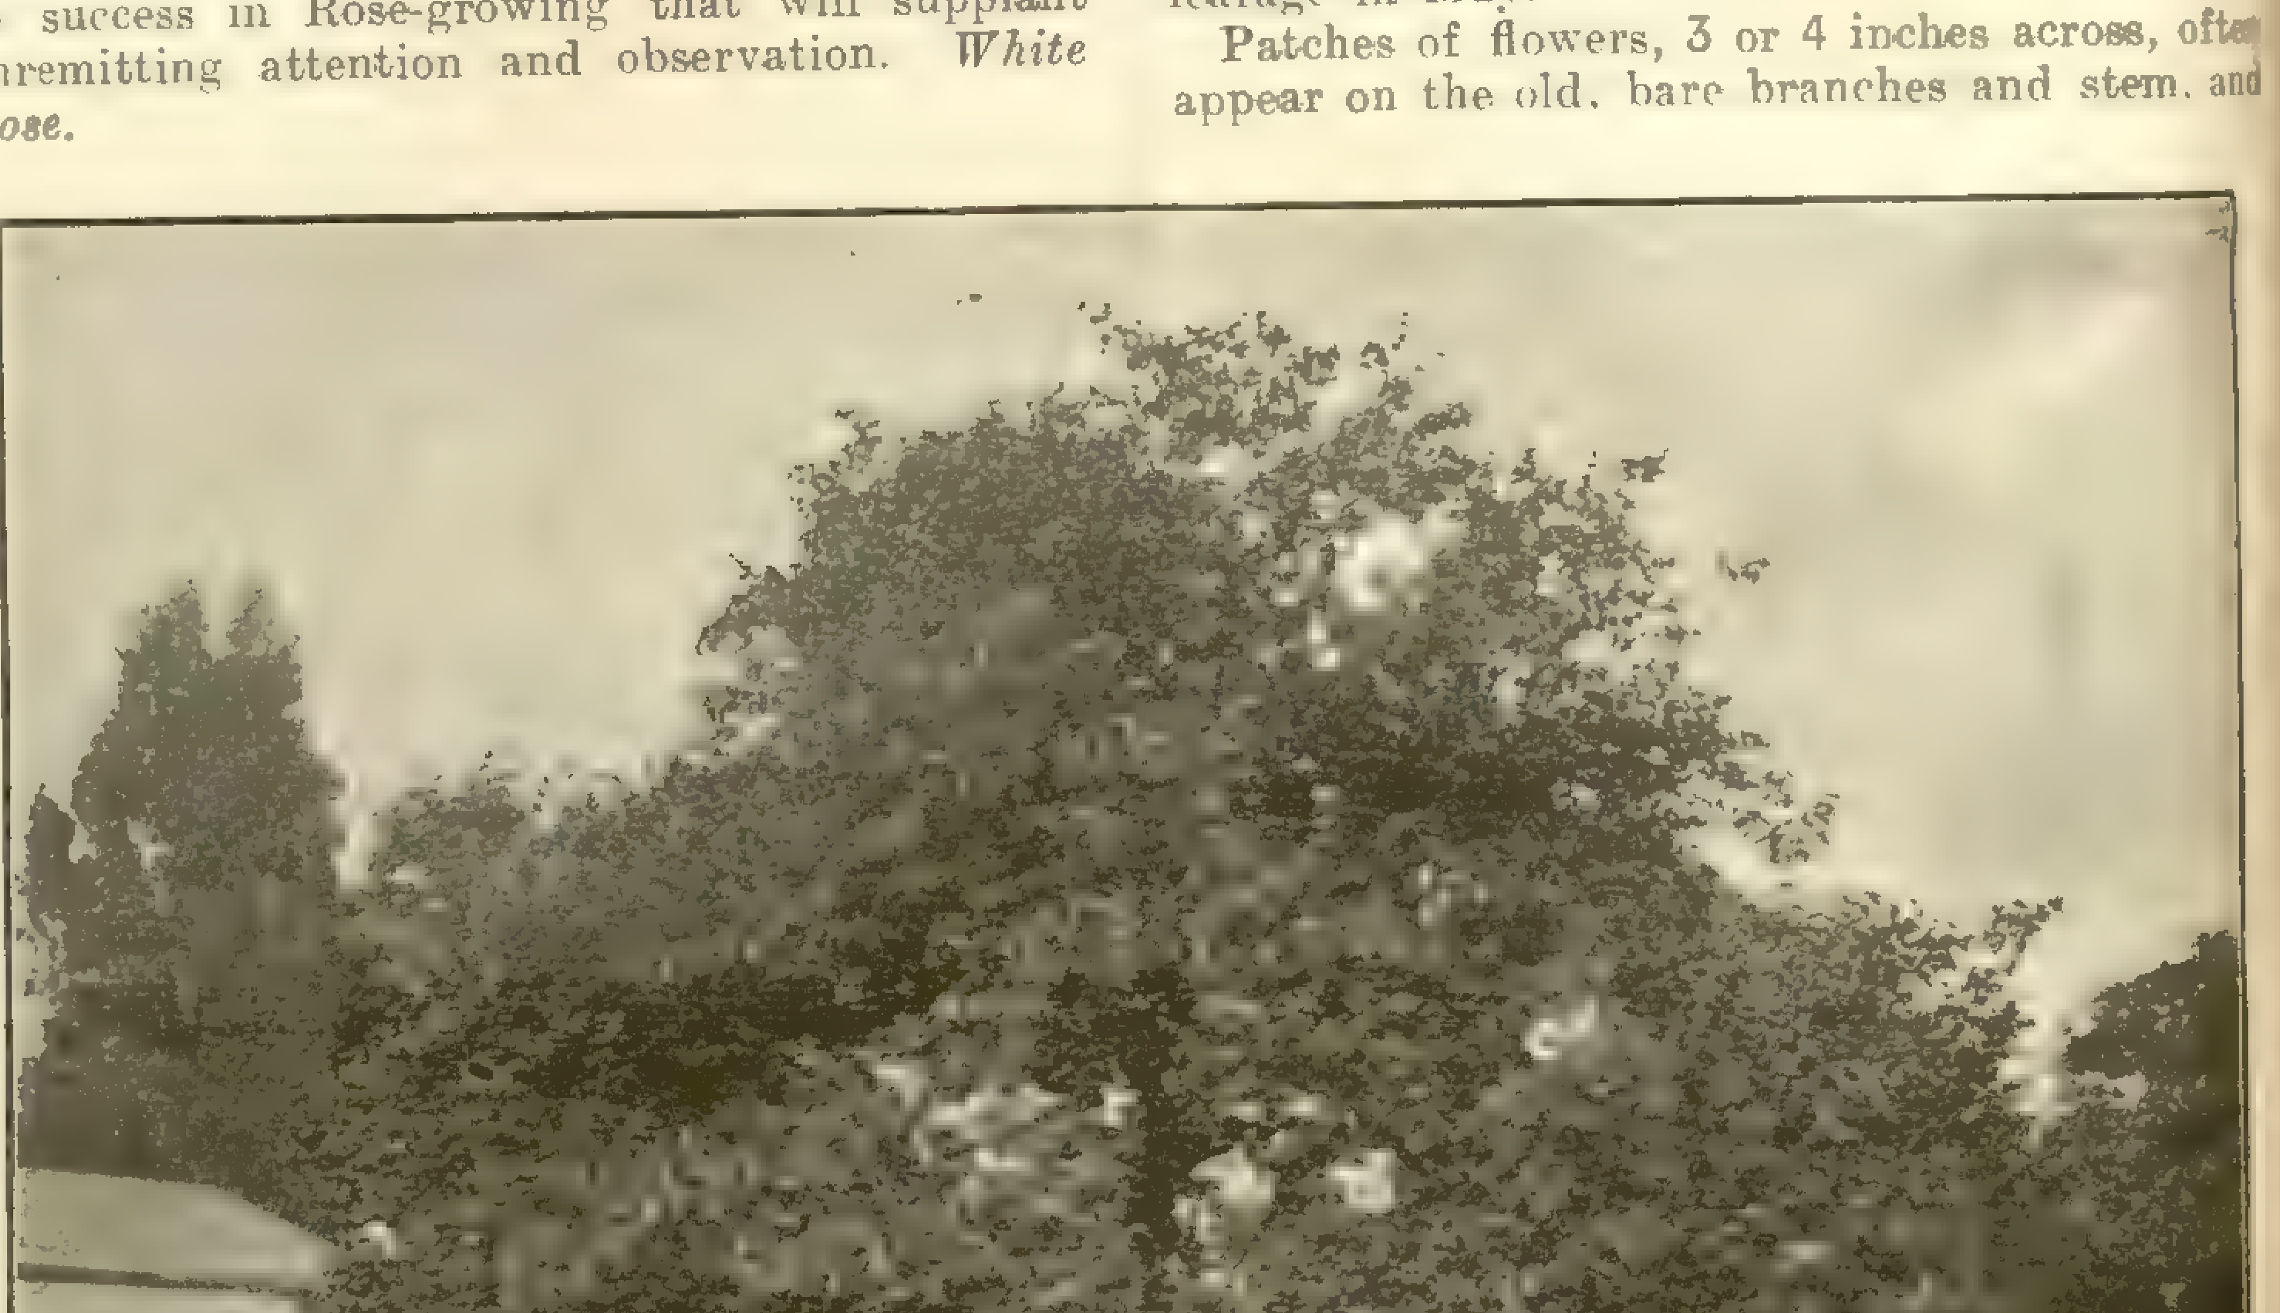

FIG. 2.—CERCIS SILIQUASTRUM IN THE GARDENS AT DOVER HOUSE, ROEHAMPTON.

TREES AND SHRUBS.

THE JUDAS TREE IN LONDON.

That the comparatively rare and strikingly distinct Judas Tree (Cercis Siliquastrum) is suitable for culture in every part of the metropolis is proved by the size and age to which specimens have attained in the grounds at Fulham Palace, in Battersea and Waterlow Parks, Golder's Green, and in several parts of the City and East End. By far the largest tree that I have seen is growing in the grounds attached to the Picture Gallery, Dulwich; it is 40 feet high, the stem girthing 7 feet 11 inches at a yard from the ground. This magnificent specimen has a tall, clean trunk, well preserved and in perfect health. Another fine tree is at Charlton House, Blackheath, the residence of Sir Spencer Maryon-Wilson; the tree has a branch-spread of 30 feet, the trunk girthing 4 feet 9 inches at a yard from ground level. Though semi-procumbent—for it was partially blown over many years ago—and the heavy branches bound together, yet this giant specimen of its kind is in perfect health and produces flowers in great abundance. Attaining in favourable conditions to a height of 30 feet, the Judas Tree in old age is often a weirdly picturesque object, the thick, usually crooked branches shooting out in all directions, and somewhat resembling those of the Catalpa and Mulberry, though in other cases it forms a comparatively broad, round, and flattish head, but its general outline can rarely be said to be either regular or ornamental. Both in shape and colour the leaves are unlike those of any other tree that I can call to mind, being of a peculiar pale, bluish-green tint above and pea-green beneath and distinctly heart or kidney shaped. They assume rich scarlet tints in autumn. The purplish-pink flowers appear before the leaves; they are clustered in small bunches on the twigs and branches, and even spring from the trunk itself sometimes downwards to near ground level. So thickly are the flowers produced that in many instances the branches seem wreathed with the conspicuous, pinky buds at the end of March and continue attractive until the tree is in full leafage in May.

Patches of flowers, 3 or 4 inches across, often appear on the old, bare branches and stem, and give the impression of having been nailed in position.

The Judas Tree was cultivated in this country as early as 1596, at which date a good illustration of it is given by Gerard, who, with reference to the popular name, remarks, "It may be called Judas Tree, for it is thought to be that on which Judas hanged himself and not on the Elder as it is vulgarly said." There is a white-flowered form and one named carnea, with beautiful, deep pink flowers. For ornamental effect in spring the Judas Tree ranks as one of the most attractive trees, owing to the beautiful and unique appearance that it presents, when both old and young wood of branch and stem is thickly studded with the purplish-pink flowers before the leaves appear. The Judas Tree likes a rich soil, and, judging from old trees at Holwood, one of Lord Derby's Kentish estates, it thrives well beneath the shade and drip of other trees. *A. D. Webster.*

[The illustration in fig. 2 shows the fine specimen of Cercis Siliquastrum in the gardens at Dover House, Roehampton.—EDS.]

SOME IMPRESSIONS OF FRENCH AND ELCIAN HUSBANDRY DURING THE WAR.

On previous visits to Belgium and France I d often admired many features of the husandry practised in those countries; during the ar I have been impressed more strongly than er by certain characteristics which I think ight to throw a light upon the problems which ce us when we come to consider the question settling soldiers upon the land. The fact at I speak as an unskilled observer and not a farmer should lend weight to my conclu-ons. The agitation in favour of a back-to-e-land policy is mainly that of people ignorant practical farming. The secret of the success farming in the countries which I have men-med—for successful it undoubtedly is—lies in e exercise of those old-fashioned qualities hich Virgil emphasises so strongly, and above things in that unremitting toil which is apt to lost sight of, or at least left in the back-und of, popular agitations concerning land. would be the worst possible service to our re-rning soldiers were we to deceive ourselves or m into supposing that the earth will yield up r riches to anything short of that *labor im-obus* which alone *vincit omnia.* Women and ildren worked upon the soil of France and soil of Belgium before the war; during war y worked harder than ever. Whether or no excessive and premature burden cast upon shoulders of the very young, the very old, d the women during the past four and a half ars prejudicially affects them is a grave ques-n; it remains that their labour unquestionably yed an important part in the salvation of ir country in her hour of need. I lived in ny a score of farm houses and cottages during e war, but in every case I found the same te of affairs prevailing, namely, the complete sence of able-bodied men, vast numbers of men and children working upon or in con-ction with the land, and old men keeping their cond foot out of the grave until their sons me home to release them. I never came into ficiently close contact with the rural popula-n before the war to understand intimately eir outlook upon life, their ideals and ambi-ns. Their single-hearted purpose in war was conquer. What mattered amusement, what attered *joie de vivre* so long as the Hun re-ained unvanquished? During the whole of y sojourn I encountered one solitary example unfettered joy in life: "C'est la guerre." remarked to an extremely ragged urchin in . Omer. "For you, yes, but not for me," re-lied the urchin. For him the war was an unend-g pageant, fraught with glorious possibilities holding officers' horses.

Second only in importance to the quality of heer hard work was that of economy of labour. never saw anything in the nature of voluntary sistance from amateurs. Yet I never saw an ich of ground left uncultivated through lack labour. The peoples of those countries possess mething which we have lost in England: one ight almost call it the earth spirit. Again and gain I wondered at and admired the magnitude the tasks accomplished by women of gentle irth. They wore no picturesque uniforms; when hey visited their friends or went to the town hey took off their working clothes and donned heir finery. In place of their coarse wooden abots they wore small and well-made boots. he transformation was so great that had one ot seen these girls actually working on the and or in the farmyard one would not have ecognised them on state occasions. It is the niversal custom for the family to live in the itchen. But what a kitchen! The memory of hose superb kitchens, with their polished brass nd copper utensils their long tables and their neffable air of homeliness and of home makes et more atrocious the wretched places where we expect our domestic servants to be happy and contented. Let it not be thought that I am following the traditional method of Englishmen in glorifying the foreigner at the expense of his fellow-countrymen; far from it. But I do seriously contend that to be a successful tiller of the soil you must be of the earth: you must know and you must, however unconsciously, love it. And you must have a constant succession of workers, from father to son, and from mother to daughter. The earth is jealous of her secrets, and does not yield them up to the chance-comer.

Is it merely a matter of habit and tradition that farm carts in England are so radically different from those of France or Belgium? Many and many a time I have wondered how those enormous vehicles which are so familiar to fighters on the Western front can be efficient. But if one of these carts will hold four or five times as much as the ordinary single-horse, two-wheeled English cart, it does not require a Solomon to see that a single carter with a team of three or even four horses will actually shift as much and usually more than four carters each of them driving one horse. When it is remembered that the distances to be traversed are great it will readily be seen how well adapted these huge farm wagons are to their particular function, and what a large number of men they set free.

But now, to mention another aspect of this important problem of economy, anybody familiar with the two well-defined types of husbandry on the Continent, namely, small holdings tilled by peasant proprietors, and large farms worked by well-to-do farmers, cannot have failed to be impressed with essential weaknesses in the former. It does not require a farmer to realise that a lot of little fields must necessarily absorb more labour than a few large ones, nor that for all purposes of distribution of produce, supply of materials, and so forth, the system of small holdings is a bad system. The only means of making it an efficient one is to pool labour and appliances. What I actually saw everywhere during the summer of 1918 was numberless small fields being assiduously hand-reaped by numberless small-holders. The result was disastrous, for speed in gathering the harvest was essential that year, as many a year before, and there was not and could not be any unity of effort in gathering it.

Few sights have ever impressed me more forcibly with the sheer mastery of man over his compeers in the animal kingdom than that of a heavily laden timber wagon drawn by a team of three horses manœuvring a sharp, narrow corner at the bottom of a steep hill in winter under the guidance of a single carter using the persuasion of voice alone. I do not know sufficient of the breeding of draught horses in this country to be able to make any useful comparison between them and those of the French and Belgian farmer. But the most casual observation could not fail to bring home to the observer of the latter their amazing efficiency, that is to say their effectiveness, in carrying out their functions. The single rein is universal, and control is exercised very largely by the voice.

One-way ploughs were also, so far as I could see, practically universal, and a very large proportion of the ploughing was done by women.

The almost entire absence of trees and hedges in the arable regions of Flanders perhaps accounts for the extraordinarily forbidding aspect of the country during the war. So long as I live I shall never forget the intensity of the longing which I felt for the green hedges and the full-grown trees of England as I lay wounded in a foreign country, nor the intensity of the satisfaction which I felt when at last I saw them again.

Are we going to make this England dear to those who come back from the war, a country where every man who is prepared to work hard and steadily can earn a decent living? Men who have survived the incredible horrors and hardships of the last few years will not shrink from toil if the future is full of promise and the present of possibilities. Our thoughts are naturally with our own kith and kin, in the first place, but one cannot help thinking also of brave, patient men and women across the water, of that endless procession of refugees streaming back as the Hun advanced in the hour of his pride; of ruined farmsteads, fruit trees systematically cut down by the ruthless invader, and of rich lands devastated by the havoc of war. Our consolation, such as it is, must lie in the irrepressible thrift and recuperative power of the Flemish peasant and the indomitable spirit of the French agricultural population. Now, if those people can, in the face of almost incredible difficulties, reclaim their lands from the flood of war, as they have proved they can, surely it is reasonable to expect that it will be our own fault if England does not once again, as of yore, nurture a race of sturdy yeomen, people born on and bred to the Earth. *Raymond E. Negus (Lt.-Col.).*

CULTURAL MEMORANDA.

WINTER WORK AMONGST SMALL FRUITS.

At this season of the year Gooseberry, Currant, and Raspberry plantations should be manured, and the bushes should be pruned at the same time. Gooseberries grown on the bush system should have the leading growths shortened about half their length and pruned to an outside bud, as this tends to keep the bushes open. Other growths should be pruned back to two or three buds from the base, but where the growths are crowded some branches should be cut out altogether. A distance of 6 or 8 inches between the branches is not too much, as this allows better facilities for gathering the fruit, and admits sunlight and air. Suckers and any growth near the ground should be removed, as berries borne near the soil become splashed and spoilt in wet weather. Some varieties of Gooseberries have pendulous growth, and these are usually supplied on longer stems than the upright growers. Plants trained as cordons or espaliers should have the leaders shortened, the laterals pruned to two or three buds, and the spurs thinned if necessary.

Red and White Currant bushes require pruning in very much the same way as Gooseberries, and should always be kept well thinned in their centres. The side growths may be cut back hard. Much finer fruit is produced on young, vigorous plants, and it is always well to have a few young bushes at hand to replace old plants that have grown too large.

With regard to Black Currants the pruning is on altogether different lines. In these the old wood should be cut out and all young wood of the previous year's growth retained, especially the shoots from the base of the plant. The great trouble with Black Currants is the mite which causes Big Bud. Where there is an attack of this pest all enlarged buds should be removed by hand and burnt, and the trees afterwards dressed with an insecticide. This will keep the pest in check, but will not altogether eradicate it. Black Currants make strong growth, and their shoots should be kept well thinned.

The Raspberry is a useful and popular fruit, and is often grown in the same quarters as Currants. The stems are usually trained to wires or poles, and the pruning consists in cutting out all canes which have fruited, preferably as soon as the fruit has been gathered. Autumn-fruiting varieties are pruned in the spring, and these fruit on the current season's growth. A space of about one foot is desirable between the shoots when they are tied, as nothing is gained by overcrowding. The Raspberry often produces

suckers some distance from the parent plant, and if these are strong and healthy it is a good plan to lift them and use them for filling bare spaces, thus keeping the rows uniform and more profitable. If new plantations are made the canes should be cut to within 1 foot of the ground, but those who desire to obtain fruits the following summer may retain every alternate plant its full length. The merits of the autumn-fruiting varieties must not be overlooked.

In the past season of fruit scarcity the small fruits proved useful and productive over nearly all the country, hence my reason for these few hints to encourage others to plant them more freely.

As all the fruits mentioned are vigorous growers and gross feeders, the ground between them should receive a heavy dressing of well rotted manure, and this should be dug in after the pruning is completed, except in the case of the Raspberry, which is surface rooting, and should have a top-dressing of manure placed on the surface, and occasionally a good dressing of old potting soil or loam. All small fruits are improved in colour and growth by the application of soot and lime, and it is a very good plan to apply these materials one season and farmyard manure the next. Too much animal dung is apt to make the ground sour, but the lime will counteract this trouble, thus keeping the ground beneath the bushes sweet and reducing the caterpillar plague. I have proved this to be the case, as our bushes were attacked by the Gooseberry caterpillar during the summer of 1917, and though they were hand picked I have no doubt many pests dropped to the ground and hibernated. Last winter, after pruning was finished, I had the ground well dressed with lime, and was much relieved to find little trace of the plague in 1918. A few caterpillars were noticed on one bush, and as these were promptly dealt with we had no further trouble. It would be interesting to know if other growers have had a similar experience. Work among bush fruits is best done when the ground is in as dry a condition as it can be in winter, and after pruning is completed all prunings and rubbish should be removed and burnt. *R. W. Thatcher, Carlton Park Gardens, Market Harborough.*

COMPOSTS.

In "Notes on Manures for December," issued by the Rothamsted Experimental Station, it is stated that in many parts of the country compost-making is now a lost art, but at one time it flourished vigorously. The type of composts that has persisted longest is the old "lime compost," made by alternating layers of vegetable or animal refuse with lime. From the old directions given by one of the chief experts of his day, it appears that the best results were obtained when lime was composted with materials poor in nitrogen, such as hedge clippings, leaves, old banks of earth, scourings of ditches, road sweepings, weeds gathered from fallows or stubbles, peat, sawdust, and roots of Couch grass. These were well mixed in the proportion of about one of lime to three of the other materials; the heap was left for a time, and then turned. Earth composts were preferred where the material contained more nitrogen than the above-mentioned substances, such, for example, as animal waste and slaughterhouse waste. The proportion of earth varied; as much as 10 cartloads of earth to one of animal waste was sometimes used; in other cases only half this quantity of earth was employed. It was, however, claimed that better results were obtained from the use of earth than from lime or farmyard manure. In the case of a dung compost no earth is used, and the materials are simply thrown into the manure heap; obviously they should be richer in nitrogen than the ordinary vegetable refuse.

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Ventilation.—Much as Orchids of all kinds delight in a full and free ventilation, the admission of fresh air may easily be over-done at this season. Choice kinds, and also many that are found difficult to cultivate, are often placed near the roof-glass, and, in small houses, this means near the ventilators, which is the most suitable place for them without a doubt. In such a situation not only do the plants get the benefit of the ventilation in full, when this is properly carried out, but they are much less liable to damping and other troubles, owing to the amount of light that reaches them on all sides. I have seen it advised to give top and bottom ventilation simultaneously during the winter, but such a proceeding is going rather too far, though doubtless airing is often underdone. When a cold wind is blowing from either side of the house it is always advisable to keep the ventilators closed tightly on the windward side. The ventilation should be continuous; small sashes that are lifted separately nearly always create draughts, and the lifting should be so arranged that the lights can be raised as little as half an inch or less if needed, and this is where geared ventilators have a great advantage over the lever and pin arrangements, which are often fixed so that it is impossible to open the ventilators less than about 2 inches owing to the first hole of the lever being that distance. To admit such an amount of air when cold, dry winds prevail is obviously a great mistake, and the use of much fire-heat to maintain the requisite temperature is equally harmful. All the moisture of the house is absorbed by the upward draught of warm air, and in such circumstances a harsh atmosphere always surrounds the heads of the plants themselves. But, on the contrary, a chink of air at the ridge the entire length of the house keeps the atmosphere of the house moving, and in consequence sweet. The possibility of cold air pressing down through the top ventilator has, of course, to be considered: but anyone with a little experience can soon tell on entering the house if this is operating, and will take measures accordingly. The above remarks apply, to a large extent, to the ventilation of all classes of greenhouses, and differs in detail when Orchids of various kinds are grown. A warm house may have for its occupants heat-loving plants that require a very moist atmosphere, and very little ventilation is needed; there may also be warm growing plants that are all, or nearly all, at rest, and in their case considerably more air is necessary. When the weather is damp and close more air is needed than when the external air is dry and cold, and the worst of all combinations is a bright sun and cold wind. The temperature of a house may rise higher than it should do if the house is closed, but it must be remembered that too much air may mean cold, chilling draughts that would give a check to growing plants, and especially seedlings, and are not without their ill-effects even on those that are resting. In such cases, open the top ventilators very slightly to allow the close, warm air at the ridge to escape, but only if it is possible on the side of the house opposite to where the wind is coming from.

Growth out of season often follows lack of ventilation now; judicious use, therefore, of the ventilators in every house is as important at this season as at any time during the year.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Arrangement of Plots.—A plan of the vegetable garden is very useful, and can readily be made, with the sites of the future crops indicated. It then becomes a simple task to prepare each plot to suit the requirements of the particular crop. If such a system is adopted

the areas reserved for tap-rooted vegetables will require no farmyard manure, provided a good dressing of burnt garden refuse and soot is applied when the ground is trenched.

Trenching.—Most gardeners realise the great value of trenching ground, in bringing the mass of earth into a friable and fertile condition quickly. Where labour is scarce for trenching proper, double digging, or bastard trenching should be practised, as deep tillage favours lasting and regular growth in the crops throughout the most adverse seasons. Both long and decayed manure should be used; the fresh dung together with rough grass and fallen tree leaves should be incorporated with the lower spit, placing the decayed manure under the top spit as the work proceeds. When the plot is dug a dressing of soot on the surface will be very beneficial. Ground treated in this manner is suitable for growing Peas, Beans, Onions, Cauliflowers, and other gross-feeding plants. When land is trenched in winter the surface should be left in the roughest state, to expose it as much as possible to the action of the weather. Trenching or digging should be done in fine, settled weather; it is much better to defer this important operation for weeks than to attempt it at inclement times.

Broccoli.—Late Cauliflowers have hearted well during the mild weather of the past weeks, but sharp frosts are occurring, and a shortage may occur from now onwards. Precautions should therefore be taken to maintain a regular supply by lifting the more forward plants of Broccoli with a good ball of earth at the roots, and planting them thickly in pits. In open weather draw the lights off entirely, unless "curds" are scarce, when every assistance should be given the plants to maintain a steady growth. It is remarkable what nice heads are obtained in this way. Winter Mammoth and Snow's Winter White are two excellent winter varieties.

Hot-Beds.—Owing to the present fuel restrictions hot-beds will be more in demand than ever. They are essential where early vegetables and salads are required. They are so easy to construct that the smallest garden need not be without one. Better results are obtained with many vegetables by forcing them on hot-beds than in heated houses. Materials for a hot-bed should consist of two parts long stable manure and three parts leaves, and they should be well mixed. The height of the beds should be not less than 4 feet, and the width should exceed the frame by 2 feet all round.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Flower Beds. — All unoccupied flower-beds should be thoroughly examined, and where the soil is known to be exhausted some of it should be removed and replaced with fresh compost, adding manure or leaf-mould, more or less according to the requirements of the plants in

tended to fill the beds during the coming season. In many gardens during the past four years very little if any flower bedding has been attempted, the majority of the beds being occupied by vegetables. When digging beds, it is not advisable to bring up the cold, clayey subsoil, but this should be disturbed to a good depth and mixed with plenty of leaf-mould, grit, or decayed vegetable refuse. The drainage of the soil should always receive the greatest attention, as ground in a sodden, sour state is most detrimental to plant life.

Renovations.—Any intended improvements or renovations in the flower garden should be taken in hand when the weather is suitable; now that other work is less pressing, labour will be available for these operations. Trenching land for the planting of trees and shrubs is most important, and is necessary if good results are expected.

Bulb Garden.—Beds which have been planted with bulbs should be kept clean and free from weeds. In very severe weather apply a layer of well-decayed leaf-mould or coconut-fibre refuse over the surface. Guard against mice damaging the bulbs, and set traps should they prove troublesome.

PLANTS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

The Fuel Problem.—The cultivation of plants under glass, and particularly exotic species requiring very high temperatures and those used for the decoration of dwelling-rooms, has been neglected to a very large extent during the period of the war. A shortage of labour

has been largely responsible for this circumstance, and now a serious shortage of fuel makes it more difficult than ever to maintain tender plants in glass-houses. Fortunately there are large numbers of plants that may be kept, healthy and serviceable, under glass, even although on nights of severe frost the temperature in the plant house is only a little above freezing-point. An absolute necessity during this period of restricted fuel allowance is to use the watering-pot as little as possible. I take the risk of the plants being over-dry at the roots rather than wet, and keep the interior of the plant house dry, taking advantage of sunshine to ventilate. When it becomes necessary to spray or syringe plants with an insecticide in houses with a low temperature first place the pots on their sides in order to reach the under-surfaces of the leaves, and keep the soil in the pots dry. Plants suitable and serviceable for the exceptional conditions under which plant houses are managed at the present time, affording decorative subjects for the greenhouse or conservatory, and also for cut flowers, are the giant-flowered forms of Primula obconica, P. malacoides (lilac and white), and P. kewensis; these Primulas, if grown in 24-sized pots, staged near the roof-glass, watered only when dry at the roots, and given a weak solution of plant fertiliser, will make a good show at the present season. In similar conditions, but in 9-inch pots, the radiata and stellata hybrids of Cineraria give a good display of flower. Bulbs, potted and prepared in autumn for forcing, may be brought indoors as required, the pots plunged in a bottom heat of 60° and forced in a temperature of 55°. The latest-flowering varieties of Chrysanthemums are still in flower. Cuttings of the decorative varieties, if not already inserted, should be planted now. A successful method of rooting the cuttings is to insert them in small pots filled with light soil, and place the pots in a box frame with a glass covering in a cold vinery or greenhouse, near the roof-glass.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Early Peaches and Nectarines. — The long continuance of wet, sunless weather has not been favourable for forcing operations. The mild weather of late autumn considerably lessened the need for fire-heat, but there was a lack of bright, sunny days, which the trees needed. As soon as

the blooms show colour the amount of atmospheric moisture in the house should be reduced, and especially keep the house dry and free from moisture during the early part of the day until the blossoms are fertilised. Rub off the blooms on the back parts of shoots on wall-trees and a fair number of those on the under-side of trees growing on trellises. By means of a soft feather brush pollinate the blossoms at midday to assist the fruits to set. Increase the temperature by a few degrees during the flowering period, ventilate the house freely on warm days, and open the ventilators a little at the top of the house both night and day till the flowers are set. Maintain a temperature of 45° to 50° at night, allowing a rise of 10° by sun-heat. This treatment will, provided the trees are healthy, ensure a satisfactory set of fruit.

Early Vines.—Vines in pots, or planted out in borders, that have made sufficient growth for the bunches to be seen, should be grown in a night temperature of about 60°, with a rise by day in accordance with the weather. During very dull days, and when the weather is cold, do not attempt hard forcing, but on bright days the temperature may be allowed to rise to about 80°. On such occasions the amount of atmospheric moisture should be increased, but not to an excessive amount, for this would cause the foliage to be flimsy and encourage the growth of tendrils and aerial roots, to the detriment of the bunches. Stop laterals at two or three leaves beyond the bunches according to the space at command, and pinch sub-laterals at one leaf.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Apple Trees.—Where the pruning of Apple trees has not been completed advantage should be taken of every favourable opportunity to get the work finished. Pruning requires to be done with great care, and the necessary knowledge can only be gained by practical experience. For

example, certain varieties of Apples, including Irish Peach, fruit at the ends of the shoots, and the operator must have a knowledge of such behaviour of varieties to accomplish the work successfully. Where summer pruning was practised not much winter pruning will be needed beyond thinning the spurs, removing all dead wood, and shaping the trees. Very hard pruning in winter has a tendency to cause the trees to make gross growth. Do not prune in frosty weather, as at such times the wood often splits and the bark dies back a considerable distance.

Mulching.—If fruit trees were not mulched in the autumn the sooner the work is done now the better. Use well-decayed manure that has been heaped during the past summer and treated liberally with manure-water from the farmyard. The dung should be spread evenly about 2 inches thick as far as the roots extend.

Pears.—The pruning of Pear trees should be completed as soon as possible. In the case of those trained on walls or trellises the ties should be examined and replaced if necessary. If time permits it is advisable to renew all clips, as these are often harbours for insects. In tying the growths, and especially young shoots, allow plenty of room for the wood to expand. After the tying is finished the borders should be cleaned, lightly pricked up with a fork, and mulched as recommended for Apples.

Winter Spraying.—Apple and other hardy fruit trees infested with insects, mosses and lichens should be sprayed whilst the buds are dormant, with concentrated alkali wash, and the work should be done during calm, dry weather. The operator should wear an old suit and rubber gloves. For Apples and Pears use the specific at the rate of 1 lb. to 5 or 6 gallons of water, and for Peaches, Cherries and Apricots 1 lb. to 8 or 9 gallons of water. I strongly recommend the use of alkali wash to all fruit growers as one of the best means of cleansing trees; it is not necessary to spray annually. I recommended that an old orchard in this district should be sprayed with winter wash last year, and the trees now would hardly be recognised as the same.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 37.8°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, January 1, 10 a.m.: Bar 29.8; temp. 41°. Weather—Dull.

A French "Kew Gardens." Our well-informed French correspondent, *A. M.*, sends us the interesting news that the project of establishing a great Botanical and Horticultural Garden rivalling Kew, which has been proposed by Messrs. G. Truffaut & Clément, is being actively supported by the powerful French Touring Club. The proposal is to create a French Kew in the park of Versailles, between the Trianon and the forest of Marly. The area in question is of 1,500 acres, and is already enclosed.

The new garden would consist of about 100 acres, devoted to botanical collections, and in the first place, at all events, would include those subjects which are absent from the gardens of the Museum of Natural History. About 80 acres would be devoted to collections of fruit trees, and 250 acres to flowers and cultivation under glass. Some 80 acres would be set apart for the installation of laboratories and for providing land for experimental purposes.

It is to be hoped that this admirable project may be realised, and that France, which has done such great work in Horticulture, may possess at Versailles a National Botanical Garden second to none in the world. The Jardin des Plantes at Paris has become so enclosed by the growth of the city that plants no longer flourish. The soil is exhausted, and the smoke of the city slowly poisons all but the most robust subjects.

We trust that the establishment of a Kew Français will commend itself to the recently appointed Council of Agricultural Stations which Monsieur Boret, the energetic and far-sighted Minister of Agriculture, has recently called into being for the purpose of co-ordinating the agricultural researches carried out in existing Experiment Stations in France. The Kew of Versailles would make an admirable central station, combining the virtues of Kew and Rothamsted, and would be comparable with the Arlington Farm established and maintained by the Department of Agriculture at Washington.

Near Paris, in a horticultural region, not far from Grignon, the site in the Park of Versailles would appear to be an ideal one. The soil is fertile, the land belongs to the State, and offers almost unlimited facilities for expansion. Furthermore, there are already at Trianon considerable collections of trees, dating from the time of Michaux.

We understand that only a year or so ago, whilst yet preoccupied with war, Germany established at or near Berlin a new station for genetical studies, called its most distinguished student of genetics to assume the direction of the station, and insisted only on one condition, that the station should be for pure research, and should not engage in work of a utilitarian nature. It would not seem too much to expect, now that peace has been restored, that France should seize the opportunity and found a botanic garden and experiment station at Versailles, which shall be worthy of her horticultural reputation and a sure guarantee that that reputation shall be maintained and made even yet more eminent. Why, moreover, if this fine project shows signs of materialising, should not some of the funds collected with the object of restoring French horticulture and agriculture be devoted to the establishment of the Research Station? For it is probable that, used thus, these funds would be of more permanent benefit to French horticulturists than if they were all expended in the detailed work of assisting individuals.

Food Imports into Ceylon, 1913-1917. The fact that so fertile an island as Ceylon is a food-importing country, and not a self-supplier—though no news to those who make it their business to watch Imperial progress—will come as a surprise to the ordinarily well-informed person. The facts of the situation are disclosed in an article* on the food supplies of Ceylon, which records in the table of imports, imports of Rice and Paddy alone amounting in 1913 to over 400,000 tons. Whilst remaining about this figure during the intervening years, they actually exceeded it in 1917.

There is, however, evidence that in some cases home food production was practised in the island during the war. Thus the importation of Potatos fell from 9,200 tons in 1913 to 4,900 tons in 1917; from which it may be inferred that Ceylon grew the odd 4,300 tons in the latter year; or it may be that Ceylon went without Potatos when transport and supplies became scarce.

The imports of sugar showed also a reduction from about 26,000 tons in 1913 to 18,000 in 1917; but here, evidently, it was not a case of self-supplying, but of doing without.

Condiments, including Chillies, Coriander, Cumin, Fennel, Garlic, Turmeric, Ginger, Pepper, Mustard, and Onions, totalled 24,000 tons in 1913 and 23,000 tons in 1917, and yet it is observed by the writer of the article from which these figures are quoted that, at all events in the case of Chillies, of which 4,500 tons were imported in 1913 and 4,300 tons in 1917, the island could supply the whole of its requirements of this condiment.

The facts as indicated would appear to call for a full inquiry. It is certain that at the call of the Mother Country many of the managers of estates joined the Imperial Forces, and that the white population was thereby so depleted that no new measures of cultivation could be adopted. Be this as it may, the result of the inquiry should suggest means for the encouragement of food production, at all events as a measure of insurance against the recurrence of the need for all parts of the Empire to be self-suppliers.

* "Food-stuffs: The Food of the Island," by F. A. Stockdale, *The Tropical Agriculturist*, Sept., 1918.

Chelsea and Holland House Shows in 1919.—Towards the close of the past year the Royal Horticultural Society circularised its usual amateur and trade exhibitors and asked them whether they would be in a position to exhibit at Chelsea in May and, or, at Holland House in July, also if able to show, what amount of space they proposed to occupy. The possibility of holding the two shows appears to depend on the tenting available, and as an alternative to two exhibitions, in May and July respectively, one show in June, either at Chelsea or Holland House, is suggested. We have no official information regarding the support promised, but, so far as we are able to judge, the trade generally will do all that lies in its power to make a horticultural success of either one or two shows, and the promptitude with which the Royal Horticultural Society has attempted the revival of its great exhibitions is generally approved.

Gift of a Park to Cheshunt.—To commemorate the end of the war Admiral of the Fleet Sir HEDWORTH MEUX has offered the property known as The Cedars, in Theobalds Park, Waltham Cross, which comprises about 10 acres, to the inhabitants of Cheshunt as a public park.

National Chrysanthemum Society. — The annual general meeting of the National Chrysanthemum Society will be held at Essex Hall, Strand, on Monday evening, February 3. The exhibition will be held on November 4, in conjunction with the Royal Horticultural Society's meeting of that date, and the Floral Committee will meet in the morning. Other meetings of the Floral Committee are fixed for September 22, October 6 and 20, November 17, and December 1, at 3 p.m., at Essex Hall.

Reopening of the Natural History Museum.—The exhibition galleries of the Natural History Museum, Cromwell Road, South Kensington, are now open to the public on week-days as before the war. During January and February admission will be from 10 a.m. to 5 p.m.

Queensland Fruits. — Almonds, Apricots, Plums, Nectarines, Quinces, Passion fruit, Papaws, Cherries, Peaches, Guavas, Persimmons, Figs, Custard Apples, Pineapples, and Pears are largely grown in Queensland, and a considerable trade is done with these in the Southern States. The adaptability of the soil and climatic conditions of Queensland to the cultivation of all varieties of Citrus fruits such as Oranges, Shaddocks, Citrons, Cumquats and Lemons is

THE LAWRENCE MEDAL OF THE R.H.S.

A portion of our Exhibit of Vegetables grown from seeds sown and Potatoes planted July 15, and staged at the Royal Horticultural Society's Meeting September 24, 1918. For full particulars see Sutton's Catalogue of Food Production Seeds for 1919. Post free on application.

AWARDED to SUTTON & SONS, READING

The Rev. W. WILKS, M.A., writing on December 11, 1918, said:—

"It is with no little pleasure that I am able to write at the request of the President and Council, to tell you that the Lawrence Medal has been awarded to your firm for the excellent quality and great educational value of your frequent exhibits of Summer-sown Vegetables at the Society's Meetings held since war broke out. The exhibits themselves have shown such a high standard of cultivation, and have been so widely influential in increasing the food production of gardens during the years of the war, by demonstrating what could be done along the lines of this new system of cultivation, that the Council feel that the least they can do, now that the war has been brought to a happy termination, is to place with you this high mark of their high appreciation. As I think you know, the Lawrence Medal represents the highest award of the Society, and it is one which is never given more than once yearly."

Published every Friday at
41, Wellington Street, Covent Garden,

Dickson & Robinson's
Garden Seeds

D. & R.'s "PREMIER" ONION. Monster bulb, and distinctly handsome. Colour, a pale straw. Pre-eminent among Onions. The prize-taker wherever shown. First Prize, R.H.S.'s Vegetable Show, 1918. 1/6 and 2/6 pkt.

D. & R.'s "ROYAL KEEPER" ONION. Keeping and croppping qualities remarkable. Skin a deep brown. Flesh mild and firm. In form, between the globe and flat sections. A distinct variety. 1/6 and 2/6 pkt.

D. & R.'s PROLIFIC LONG-POD BROAD BEAN. Early and very prolific. Finely-shaped long pods, containing 8 to 10 beans. First-class flavour. An exceedingly good variety. For table and exhibition. 1/9 per pint. 3/6 per quart.

D. & R.'s GIANT EXHIBITION RUNNER BEAN. Fleshy, tender, deliciously-flavoured pods—measuring up to 15 inches—produced in clusters. First Prize R.H.S.'s Vegetable Show, 1918. Pint 2/6.

D. & R.'s "LITTLE GEM" CARROT. Earliest, and most suitable for forcing. Almost round; bright red; small top; sweet, tender flesh; nearly coreless. Pkt. 9d.; ounce 1/6.

D. & R.'s "AVIATOR" TOMATO. 8 to 12 fruits to a bunch, 8 to 10 bunches to a plant. Solid, smooth fruits. Admirable colour, shape and flavour. About 6 fruits go to the pound. A healthy and robust grower. Very short jointed. 6d. and 1/- per pkt.

D. & R.'S "THE CROPPER" CUCUMBER. Only slightly spined. 18 to 24 inches long—dark green—well made up at the shoulder—regular in size—same thickness throughout. Sets its fruit well, and carries bloom well when cut. 1/6 pkt.

D. & R.'s "EXHIBITION" LEEK. Immense size, and most agreeable flavour. Long, thick, pure white stems. 1/6 per pkt.

D. & R.'S NEW WINTER KALE Stands severest weather. Best at end of January or early February. Dwarf, compact growth. Dark green leaves, exquisitely curled. Comes after other kales. No better "catch" crop. 1/- pkt.

D. & R.'s EXCELSIOR CREAM VEG. MARROW. A grand addition to the Marrows—the best of the "creams." Fruit handsome. Colour, delicate creamy-white. Very thick flesh. Highly commended in the Trials of the R.H.S. 1918. 1/- pkt.

AND ALL OTHER SEEDS.

SEEDSMEN BY ROYAL WARRANTS TO HIS MAJESTY KING GEORGE V AND TO HER MAJESTY QUEEN ALEXANDRA

Cathedral Street,
MANCHESTER.

demonstrated by the fact that no fruit, unless perhaps the Mango, is more generally distributed or has a wider range in the State than the Citrus family, even on the table-lands, where heavy frosts are experienced. The Banana is universally grown on the coastal lands of Queensland, and Bananas thrive and bear well in North Queensland several hundred miles inland.

Presentation.—At the meeting of the Coventry Gardeners' Federation, held on the 16th ult., a presentation, consisting of an engrossed letter, framed in Oak, together with a wallet containing Treasury notes, was made to Mr. E. G. MORRELL in recognition of his work in connection with the allotment movement in Coventry and neighbourhood during the past seven years. The presentation was made by Ald. H. MANDER, in the presence of representatives of the different societies affiliated to the Federation, of which Mr. W. B. RAINBOW is the secretary. Mr. MORRELL suitably acknowledged the presentation, and spoke of the pleasure it had given him to assist in the furtherance of the allotment movement.

£15,000,000 Worth of Produce from Allotments.—At a Conference of the Southern Section of the National Union of Allotment Holders held at Essex Hall recently, Mr. J. FORBES, the secretary, stated that there were one and a half million allotment holders in the country, and the estimated aggregate value of the produce from the allotments was £15,000,000. The Conference passed resolutions urging the Government to place the allotment movement on a permanent basis, and to provide for allotments in connection with any housing scheme brought forward.

Sale of Red Cross Tree for £1,300.—A fine tree, presented by the Duke of BUCCLEUCH, has realised £1,300 for the Red Cross Gift Tree Sale which is being voluntarily organised by Messrs. RICHARDSON, of Stamford. A tree given by the Duke of RICHMOND AND GORDON has sold for £100. The KING'S tree, from Windsor Park, will, it is hoped, be purchased and re-offered for sale by generous people who desire to assist in augmenting the Red Cross funds.

Flowers in Season.—The receipt of a few fine flowers of Iris unguicularis (so well known in gardens as Iris stylosa) from Mr. JAS. A. PAICE, Aldenham Vicarage Gardens, Watford, serves as a reminder of the beauty and usefulness of this winter-flowering species. Mr. PAICE informs us that the plants under his care are flowering magnificently, and, owing to the mild weather experienced, they commenced to bloom earlier than usual this winter. He writes: "I am never tired of praising this beautiful winter-flowering Iris. At Aldenham Vicarage it has been established for several years close to a south wall, where it flowers from November to March without intermission. Very hard frosts and snow check continuity of flowering a little, but for no length of time. The flowers are best cut while in the bud state and placed in water indoors to open; when cutting the blooms the knife should be inserted as low down as possible, to secure a long stem; cut in this way they last longer than when removed carelessly a little above the ground. When planting, no manure should be used, as the plants flower best in poor, somewhat stony soil. Plants of this Iris may be grown fairly closely together and should not be disturbed more often than is absolutely necessary. I have noticed that I. unguicularis blooms freely after a dry summer, thus proving that it requires a thorough rest. Large numbers of flowers must not be expected until the plants have been established for a year or two. There is a beautiful white variety which will succeed if treated in the same way as the type."

Food Production in the Panama Canal Zone.—Everything possible is being done by the United States Government to make the Panama Canal zone self-supporting, especially as regards food production. Large areas of land have been laid out for the cultivation of fruits and vegetables, sufficient grazing land has been cleared and fenced to provide for the fattening of 25,000 head of cattle, and cold storage provided for the preservation of meat, fruits and vegetables.

Grevillea Thelemanniana.—Grevillea Thelemanniana (see fig. 3) has just claim to be placed among the most beautiful of cool greenhouse plants, and it is a regrettable fact that it is so seldom seen in cultivation. The plant is of comparatively easy culture, and, unlike most Grevilleas, it proves particularly useful for growing in small pots. Of neat and graceful habit, the plant produces its racemes of flowers with such freedom that it compares most favourably with any other occupant of the greenhouse; moreover, it flowers over a very long period and is rarely out of bloom. Grevillea Thelemanniana is readily raised from cuttings or seeds. The cuttings should be moderately firm shoots and

FIG. 3.—GREVILLEA THELEMANNIANA: FLOWERS PINK, TIPPED WITH GREEN.

inserted in a sandy compost in the autumn. The blooms are borne in terminal racemes about 4 inches in length; they are coloured pale satiny-pink, tipped with green, and are rendered additionally attractive by the long, red, protruding style. The pinnate leaves are highly decorative, from 1 to 2 inches long, and slightly ribbed. This species is figured and described in *Bot. Mag.*, t. 5,837, under the name of G. Preissi, and was first flowered at Kew in 1870 from seeds sent by Mr. DU BOWLEY, of Perth, Australia, where the species was found by PREIS and other collectors. G. Thelemanniana is usually in flower in the Greenhouse (No. 4) at Kew during the greater part of the year.

American Control of Hawaiian Sugar Production.—Sugar production, the most important industry in the Hawaiian Islands, has long been very largely under the control of the Messrs. H. HACKFIELD Co., a German-owned corporation which controlled at least ten other companies. Now, as a result of the action of the Alien Property Custodian of the United States, the powerful German interests have been eliminated and the business taken over by a new American company known as AMERICAN FACTORS, LTD., financed by 640 American residents of Hawaii. All shareholders have to satisfy the authorities as to their loyalty, as it is believed the HACKFIELD COMPANY was the centre of German propaganda in the Pacific.

Life in the Arctic.—A recent issue of the *Daily Express* contains an interesting account of an interview with Mr. V. STEFANSSON, who has just returned to New York after spending five and a half years in the American Arctic archipelago at the head of an expedition sent out by the Canadian Government to explore the islands and seas north of Alaska. Mr. STEFANSSON says that, contrary to popular impression, the Arctic regions are not barren of life, and that there is no place on earth where it is easier for a man to support himself if he knows how. There is abundance of game everywhere, he said; there are polar bears and seals on floating ice in the lanes of open water. On land there are musk oxen and reindeer or caribou. "Every polar island that I have seen is covered with grass and vegetation, upon which fat herds of reindeer and musk oxen feed." Mr. STEFANSSON and his party traversed about one-quarter of an unexplored region embracing some one million square miles 400 miles from the Pole. It had always been considered the most inaccessible part of the northern hemisphere. The members of the expedition travelled on an average more than 2,000 miles a year for five years and never missed a meal and never lost a dog from hunger.

Hydrogen cyanide in Burma Beans. — As some cargoes of Burma Beans were found to be of a poisonous character, the Burma Department of Agriculture was urged to encourage the cultivation of Beans containing less cyanide than Phaseolus lunatus. As the result of experiments, reviewed in Bulletin No. 79 of the Agri-

cultural Research Institute, Pusa, it has been found that Madagascar Beans are not suitable for replacing the Pe-gya and Pe-byungale Beans so largely grown in Burma, and, moreover, after two years' cultivation their prussic acid content increased. From tests made with special cultures of the common Pe-gya Bean it is concluded that those with a low hydrogen cyanide content give low figures when grown in different localities, but the content varies considerably with different soil and climatic conditions.

Agricultural and Horticultural Training for Soldiers in France.—2nd Lieut. W. HALL and Sergt. A. H. RIDOUT write from the 49th Division School of Agriculture and Horticulture, at Douai, as follows: "We should be pleased if you will allow us to state in the *Gard. Chron.* that we are just starting agricultural and horticultural courses in this Division, pending demobilisation, which, of necessity, may take some time. Our aim is to give practical instruction both in farming and gardening, and we have been given the use of the French Agricultural and Horticultural School, close to Douai. In the case of farming little will be possible at present except the preparation of the land for Potatos and root crops, which will constitute the practical side, with lectures dealing with the scientific side. Regarding horticulture, we have some good material to work on, notably a finely laid out garden of about 4 acres, well stocked with a splendid lot of trained fruit trees in first-rate condition. Here we shall be able to do practical work, in conjunction with lectures, all of which we hope will be very beneficial to the students, who will have good billets and a lecture and recreation rooms. The most difficult things to obtain at present are suitable books and papers on farming and gardening, hence we venture to appeal to the generosity of your readers who may have any spare copies of either books or papers on these subjects, or any spare reading matter, which we could add to the stock of our library and reading-room. If such literature is made into a parcel, addressed to the 49th Division, School of Agriculture and Horticulture, B.E.F., France, and handed in at the nearest Post Office, it will be greatly valued by the lads who have done their bit in the fighting and are looking forward to doing equally well in helping to make the land of 'Old Blighty' more productive."

Canadian Apple Package and Grading.—As a result of action taken at a convention of representatives of the Canadian fruit industry, the Canadian Government has passed an Act raising the standard of Apple grading, and also providing for certain changes in the legal size of Apple barrels and boxes. The following regulations, which came into force on January 1, 1919, prescribe the dimensions of Apple packages: All Apples packed in Canada for sale by the barrel, in closed barrels, shall be packed in good and strong barrels of seasoned wood of the following dimensions, as nearly as practicable: length of stave, 28½ inches: diameter of head, 17⅛ inches; distance between heads, 26 inches: circumference at bulge, 64 inches outside measurement, representing as nearly as possible 7.056 cubic inches. All Apples packed in Canada for sale by the box shall be packed in good strong boxes of seasoned wood, the inside dimensions of which shall be: length, 18 inches; width, 11½ inches; depth, 10½ inches, representing as nearly as possible 2,174 cubic inches. It may be explained that these regulations have the effect of assimilating Canadian to American box and barrel standards. The American box, 18 inches by 11½ inches by 10½ inches, holding 1 bushel, will take the place of the long British Columbia box, 10 inches by 11 inches by 20 inches, of about the same capacity, previously seen on the market. The larger Ontario and the smaller Nova Scotia barrel will give place to the American standard barrel, holding 3 bushels. The following grading regulations are now in effect:—Grade 1.—No person shall sell, or offer, expose or have in his possession for sale, any fruit packed in a closed package upon which package is marked "No. 1" unless such fruit includes no culls and consists of well-grown specimens of one variety, sound, of not less than medium size and of good colour for the variety, of normal shape and not less than 90 per cent. free from scab, wormholes, bruises and other defects, and properly packed. Grade 2.—No person shall sell, or offer, expose or have in possession for sale, any fruit packed in a closed package, upon which package is marked "No. 2," unless such fruit includes no culls and consists of specimens of not less than nearly medium size and some colour for the variety, sound, and not less than 85 per cent. free from scab, wormholes, bruises and other defects, and properly packed. Domestic Grade.—No person shall sell, or offer, expose or have in his possession for sale, any fruit packed in a closed package, upon which package is marked "Domestic," unless such fruit includes no culls and consists of fruit of not less than medium size for the variety, sound, and not less than 80 per cent. free from wormholes (but may be slightly affected with scab or other minor defects), and properly packed. Grade 3.—No person shall sell, or offer, expose or have in his possession for sale, any fruit packed in closed package, upon which package is marked "No. 3," unless such fruit includes no culls and is properly packed. Culls, which are excluded by the preceding regulation, are defined as follows: "Culls" means fruit that is either very small for the variety, is seriously deformed, or has 15 per cent. or more of its surface affected by any of or by the combined injuries caused by Apple scab (Venturia pomi), insects, cuts, bruises, or other causes, or the flesh of which is not in an edible condition, or the skin of which is broken so as to expose the tissue beneath. The attention of importers is called to the fact that, by these amendments, the standard of No. 2 Apples is raised by the requirement of 85 per cent. freedom from defect instead of 80 per cent. as formerly, and by the prescription of a colour requirement heretofore not called for, that the unofficial grade known variously on the British market as Large No. 3, Paper Label No. 3, or Co-op. No. 3 is now legalised as the new Domestic Grade, and that the standard of No. 3, formerly interpreted as anything merchantable, not included in the higher grades, is considerably raised by a careful definition of "culls," which must be excluded.

Eucalyptus.—The 35th part of MAIDEN's *Critical Revision of the Genus Eucalyptus* deals with the following species: E. Lehmannii, E. annulata, E. platypus, E. spathulata, E. gamophylla and E. argillacea. These are all confined to West Australia, except E. gamophylla, which has also been collected within the south-western border of South Australia and perhaps in the Northern Territory. All the species are shrubby or trees of only small dimensions. E. Lehmannii is remarkable in having the flowers and seed vessels embedded in the thickened stalk, forming a concrete mass in the fruiting condition. The handsome cultivated plant figured in the *Botanical Magazine* (plate 6140) as E. cornuta, Mr. MAIDEN refers to E. Lehmannii. E. platypus (HOOKER's *Icones Plantarum*, plate 894), of this affinity, is distinguished by its singularly flattened, usually curved peduncles, bearing from 3 to 7 sessile flowers. E. gamophylla is one of the few species of Eucalyptus having opposite leaves through all stages of its growth, and these vary greatly in size and shape, even in the fruiting stage. The broader conditions resemble the connate upper leaves of Lonicera Caprifolium.

"Plant Immigrants." — Several interesting plants are cited in No. 138 of *Plant Immigrants*, U.S.A. Actinidia arguta is stated to be an excellent climbing shrub suitable for planting in the neighbourhood of New York. A very vigorous grower, it will cover a trellis 20 feet long and 10 feet high in two or three years, but the plant does not (at least in Maryland) flower freely until six to eight years old. The flowers are attractive, with their white petals and dark stamens, and the flavour of the fruits is sweet, pleasant, and Fig-like. A hybrid between Berberis Wilsonae and B. aggregata is of even more spreading habit than the former species, and has dense foliage which turns deep purple at the approach of frost and remains on the plant till mid-winter; a handsome and hardy plant. Brassica pekinensis (Pai ts'ai), from China, is said to be a rapid grower, coming to maturity in four, or at most six weeks from germination. It has a "buttery" flavour, and is prepared by dropping into boiling water after cutting into large pieces. Phaseolas aureus, also from China, produces edible sprouts when grown in a moist, warm, dark place. A Chinese race of Pea, Pisum sativum, is grown as a winter crop on Rice lands in the Yangtze Valley. It is sown in October and harvested in April; a variety with which hybridists in search of a hardy Pea for winter sowing should experiment. Rubus bogotensis, from Columbia, is said to excel all Blackberries in flavour. A Broad Bean (Vicia Faba) also is grown as a winter crop in China, and its seeds make a nutritious and palatable dish.

Publications Received. — ***British Rainfall, 1917.*** By Hugh Robert Mill and Carle Salter. (London: Edward Stanford, Ltd.)

ORCHIDS IN 1918.

ORCHIDS were extensively and consistently exhibited at the meetings of the Royal Horticultural Society in 1918. Messrs. Armstrong and Brown, Messrs. Charlesworth and Co., Messrs. Stuart Low and Co. staged large exhibits of excellent quality. Messrs. Armstrong and Brown were awarded a Gold Medal at the closing meeting of the year for a specially fine collection. Of the many and interesting plants submitted to the Orchid Committee for awards seventy-seven gained that distinction, twenty-one received First-class Certificates, thirty-three Awards of Merit, twenty-one Preliminary Commendations for seedlings flowering for the first time, and one a Certificate of Appreciation. The pictures of certificated Orchids, each with its name, date of award, derivation, and other data, in the Society's collection number 2,439. These illustrations form a valuable source of reference, and serve to demonstrate the progress of Orchid hybridisation. In the aggregate the awards are equal to those of 1917, but it is satisfactory to note that the number of First-class Certificates is more than double that of the previous year's record, and the general character of the exhibits show good progress.

Of the plants which were awarded the First-class Certificate Sir Jeremiah Colman, Bart., exhibited two of the best in Brasso-Laelio-Cattleya Antoinette Gatton Park variety and Brasso-Cattleya Gatton Lily; C. J. Lucas, Esq., in Sophro-Laelio-Cattleya warnhamensis, showed the best and brightest Sophronitis cross; Dr. Miguel Lacroze, in Cattleya Monarch Bryndir variety, had a massive variety of a very showy Cattleya; and John Hartley, Esq., in Cypripedium John Hartley, showed great progress in this class. Messrs. Armstrong and Brown excelled among nurserymen, their Laelio-Cattleya President Wilson, Odontoglossum Lady Veitch, Miltonia Lady Veitch, and Odontoglossum promerens xanthotes, all of which received First-class Certificates, being noble plants. The firm were also awarded twelve Preliminary Commendations for seedlings of great promise.

Messrs. Charlesworth had as their best plants the very fine Odontoglossum St. James, Cattleya Clotho var. General Pershing and C. Britannia Majestica.

Messrs. Flory and Black produced several very

fine novelties, including Cattleya Hardyana alba var. President Wilson and Brasso-Cattleya Princess Mary; Messrs. J. and A. McBean showed the pure white Cymbidium Alexanderi album and the richly blotched Odontoglossum eximium Le Papillon.

The list of plants for which Awards of Merit were given includes many destined for the higher Award when mature, and the Preliminary Commendations show that, especially in Odontoglossums and Odontiodas, the work of evolution is being continued satisfactorily.

It is to be regretted that but few species or varieties of species were entered for awards, and not a single award to a species was made, whilst only three varieties of Odontoglossum crispum (home-raised seedlings), viz., O. c. Oakwood Triumph, from Mrs. Cookson; O. c. The Britisher, from Mrs. Ogilvie; O. c. Beauty of Ashtead, from Mr. Ralli, secured Awards of Merit. The perfectly shaped O. c. The President from Messrs. Charlesworth and Co. gained only a Preliminary Commendation. There are sufficient reasons why Orchid species should be scarce, and importation for some time will be difficult, but it is to be hoped that the importation of Orchids from their native habitats will be taken up again at the earliest opportunity, for it must be remembered that a very large class of gardeners still require showy, imported Orchids, and there are many lovers of pretty botanical species. The importation of plants in the near future will probably be handicapped by restrictions of freight and collecting, but against that it may be said that access to new countries opened up during the war gives better prospects of discovering new species.

In *The Gardeners' Chronicle* lists of new hybrids during the past year two hundred and fourteen new crosses have been registered, compared with two hundred and sixty in 1917. The methods disclosed are similar to those of the past, and old favourites, such as Cattleya Dowiana aurea and Odontoglossum crispum and their descendants are largely used as parents, but the crossing generally is regulated, necessarily, by the plants in flower at the same time, advantage being taken, when possible, of a desirable kind flowering out of season.

Those who are engaged in the work continuously must have acquired many interesting facts which would tend to throw light on the subject of hybridising, and they would aid in making the methods adopted more scientific by communicating their observations to the horticultural Press. Facts of great interest have been recorded relating to the production of albinos, yellow hybrids, and on the possibility of the labellum, generally the richest in colour, taking part in heightening the colour of the other segments in the progeny under certain conditions. In *Gard. Chron.*, March 28, 1914, under Epi-Laelia Medusae, were given interesting particulars of the manner in which deep laceration in the lip of one parent was filled with membrane in the hybrid, quite changing its character. The crumpled, fimbriated lip of Odontoglossum Hunnewellianum, in successive crossings with plain-lipped species, has resulted in an abnormal, almost circular, development of the lip (Odontoglossum crispothello) (*Gard Chron.*, May 11, 1918, p. 194), evidently from the expansion of the many folds in the lip of one species by the firm structure of the other. The crumpled lip of O. Hunnewellianum, O. Adrianae and O. luteo-purpureum were thought to be floral defects by many Orchidists, but the art of the hybridist, if correctly exercised, may get advantages even from so-called defects.

In the early days of hybridising the male and female parents were always noted. This record is very important if results are to be accurately estimated, and even if the male parent is unknown, the name of the seed-bearer should be carefully stated when plants are sent for registering. The following new and noteworthy Orchids have been illustrated in *The Gardeners' Chronicle* during 1918:—

Aerido-vanda Mundyi, March 2, p. 93.

Brasso-Laelio-Cattleya Antoinette Gatton Park variety, December 7, p. 229.

Catasetum Darwinianum, male and female flowers, August 10, p. 61.

Cattleya Iris Ansaldo's variety, September 7, p. 101.

Cattleya Venus The Knowle variety, October 5, p. 136.

Cirrhopetalum ornatissimum, September 28, p. 131.

Coelia macrostachya, August 31, p. 91.

Cynorchis purpurascens, March 23, p. 122.

Cypripedium Eurybiades Shillianum, February 16, p. 72.

Doritis pulcherrima, February 9, p. 57.

Laelio-Cattleya J. F. Birkbeck Fowler's variety, May 18, p. 209.

Laelio-Cattleya Linda, November 9, p. 189.

Laelio-Cattleya Oenius Bryndir variety, January 19, p. 27.

Lycaste Deppei, April 13, p. 154.

Lycaste Imschootiana, August 24, p. 77.

Miltonia Lady Veitch, June 22, p. 257.

Neomoorea irrorata, March 30, pp. 134, 135.

Odontioda Memoria F. M. Ogilvie, February 23, p. 81.

Odontioda Windsor, March 16, p. 115.

Odontoglossum Corona, February 9, p. 53.

Odontoglossum crispum Oakwood Triumph, April 27, p. 174.

Odontoglossum Gatton hybrids, variation in, July 20, p. 22.

Odontoglossum Hamlet, June 29, p. 262.

Odontoglossum Jasper var. Roehampton, April 13, p. 160.

Odontoglossum Lady Veitch, November 30, p. 216.

Odontoglossum Peerless var. Jas. MacNab, June 22, p. 252.

Odontoglossum Victory The Baroness, May 4, p. 184.

SOIL CULTIVATION.

In the case of medium and strong loams, as well as clays, autumn and winter tillage are preferable to spring cultivation, for rain and frost are valuable agents of soil-disintegration and hence of soil-fertility. This work may be carried to three degrees, and it is for the individual cultivator to decide which is best suited to his particular circumstances. The first is ordinary digging, which should give a depth of 12 inches; the second is bastard trenching, with a depth of 20 inches or more; and the third is trenching with an equal or greater depth. Of these the last-named is the best if the subsoil is sweet; the second if there is any doubt as to the condition of the subsoil, whilst the first should only be done where the land is very shallow or overlies rock. Whichever system is chosen for adoption, the top soil should be turned as roughly as possible and left to the action of the weather. On no account should heavy land be wheeled over, unduly trampled on, or dug during wet weather, or when water is standing on the surface, as this would of a certainty lead to its working very badly for at least one season, and most probably for some time longer. In the case of light soils that lack the necessary power of holding plant food, loosening is undesirable, and efforts should be directed towards consolidation. As autumn loosening would encourage the percolation of water through the soil, it is wise to defer working such ground until the spring, and then do it as early as the condition of the land will permit. After manuring, to which attention will be drawn forthwith, the soil should be carefully and thoroughly firmed before sowing or planting. This matter is worthy of attention from growers, for if the digging is done when the soil is in the proper condition of moisture, it cannot be productive of anything except good to the plants that are grown. The preparation of the soil is the first and most important factor; all experienced growers understand the value of thoroughly working the soil in autumn or early winter and again before planting. Re-digging may be necessary, if the soil be stiff, before it is brought to a proper tilth. The deeper light, sandy soil may be worked the longer will it hold moisture, and, as a consequence, the longer will plants continue to grow in dry weather. We can therefore realise at once the paramount importance of deep trenching.

As strong soils are cultivated in the autumn so also must they, wherever possible, be manured in the autumn, and the finest manure is horse-dung which has been kept for some time. If the soil is simply dug the manure should be put at the bottom of the trench, but if either bastard trenching or full trenching is adopted the manure should be thoroughly incorporated with the second spit. In this form of manuring the entire plot of ground allocated to such crops as Cabbages, Onions and Leeks would each receive a portion, and I am convinced that this is the correct system to adopt, but where manure is scarce it can be placed either in stations or trenches, according to fancy, and it should be be mixed with the second spit and not laid in solid masses.

The depth at which the manure will lie depends upon the nature of the soil, but, as a rule, it should not be nearer than a foot to the surface nor deeper than 2 feet. Soils of a light nature are worked and manured in the spring, and the object should be to incorporate such materials as will add to the retentiveness of the ground, and for this purpose nothing is better than well-decayed cow manure, as it is naturally cool and moisture-holding.

We have still, however, to consider the indispensable special or concentrated fertilisers. Generally speaking, the finest results that accrue upon their use follow spring application, but at the same time there are one or two that are best applied in autumn. Basic slag is very slow in action, and is practically valueless applied after the end of January, and only of full value when worked in the soil before the end of December. It should be used at the rate of 5 ozs. to the square yard. Kainit may also be applied early because it is not readily washed out of the soil. It should be used at the rate of 4 ozs. to the square yard.

For spring application superphosphate of lime is the best form of phosphatic fertiliser; the best form of potassic food is sulphate of potash; and the best forms of nitrogenous food nitrate of soda and sulphate of ammonia. For pricking into the surface of strong soils about the end of February or early in March use a mixture consisting of three parts of superphosphate, two parts of sulphate of potash, and half a part each of nitrate of soda and sulphate of ammonia; the quantity used should be 2 or 3 ozs. to the square yard.

The materials should be mixed thoroughly, and when worked in the soil with a spade the operator should endeavour to get them evenly distributed over the whole area of the ground. Nitrate of soda or sulphate of ammonia alone will have not the slightest value at that early time of dressing; if it is inconvenient to obtain both do not use either as a food, but reserve it for application as a stimulant at a later stage of the plant's progress. The best time to apply lime is in the autumn. It is worth while also to give another dressing of lime early in the spring. Soot is a valuable fertiliser, and should be applied several times during the season. *James A. Paice.*

ON INCREASED FOOD PRODUCTION.

SUNFLOWERS FOR SEED.

THE note by *A. N.*, on p. 220, Vol. LXIV., on the growing of Sunflowers for seed interested me. The planting of Sunflowers for this purpose was strongly advocated last spring by the Food Production Department. I planted about 4 rods of land with Sunflowers; the seeds were sown the last week in April on a newly broken up tennis lawn; the soil, a sandy loam, was well manured and prepared. The rows were made 3 feet apart and the plants thinned to 2 feet asunder in the rows. They grew splendidly, many of them reaching a height of 14 feet, and most of them developed large flower-heads. In September we had a heavy gale (as we generally do), which laid more than half of the plants. A few seeds matured on those that were left upright, which the tits and finches finished off for us. Thus the result of my Sunflower patch was nil. Had I planted Potatos, as I did on the other part of the ground, I should have had another 8 cwt. of tubers. This recommending of experiments with Sunflowers, Sugar Beet, Maize, or, as it was boomed by some firms, Sugar Corn, was a great disappointment to many small growers who take their gardening hints from daily papers. It would have been far better if the experts had advised them to concentrate on well-tried subjects, which would have given them good returns for their labour, and have added to the food supply of this country in a time of scarcity. *W. H. Fraser.*

SEAWEED.

I CAN substantiate the experience and opinion of *Yorkshire* (p. 220, Vol. LXIV.) as to the value of seaweed for certain vegetable crops, and would go further, to say that most crops would be benefited by it, but especially those that readily respond to an application of a manure containing potash. Much seaweed was formerly burned for kelp, which is rich in soda and potash. On the shores of the Moray Firth and other parts of Britain it is much used for growing Potatos, whilst in the northern district named it was much used by local farmers. In some cases it was procured in summer and mixed with soil till the time of ploughing, but in many other cases it was carted directly on to grass land, spread and ploughed in without any preparation. Its use gave heavy crops of Corn, Turnips and grass for a number of years, after which the weight of produce lessened considerably. This was thought to be due to sand on the seaweed, that made the soil too light. I think the excess of potash was responsible for depleting the store of other necessary plant foods in the soil, and that superphosphates, and nitrates, or even farmyard manure, applied alternately with the seaweed, would have restored the balance. A plentiful supply of seaweed would indicate a rocky sea bottom, not far from a low or shelving beach, where the tides would cast up the old and detached plants of Fucus, Chondrus crispus, Rhodymenia palmata, and others, in quantity. *J. F.*

SEWAGE AS MANURE.

IN these days of scarcity of stable manure prejudice as to the use of home resources will have to be abandoned, and gardeners should begin to realise that sewage sludge is a valuable winter manure.

Sewage alone is not, perhaps, a complete manure. It needs potash, and this can be added in the form of flue dust, which also has the advantage of possessing pest-killing properties, if quite fresh. About a one-eighth part of flue dust should be added, and the material dug in as soon as possible. If flue dust is not available, wood ash might be mixed with the sludge. The sewage should be spread on the ground at the rate of about 1 ton or a little more per 300 yards, and dug in.

I do not advise the use of what is known as unpressed tank sludge. As a rule it contains too much water to be of use, and its unpleasant odour makes it objectionable for spreading on the land unless it can be dug in immediately or stored in an out-of-the-way place. The material to which I refer is that which has been precipitated and pressed, and which does not contain a large percentage of water. The water content is not nearly so great as in fresh cow manure, so that a ton of the sludge will contain more manurial value than a ton of fresh cowdung.

Potatos and Peas yield excellent crops when this manure is used, and also most tap-rooted crops, especially Globe Beetroot, Swedes, and Sugar Beet. Parsnips are not quite so good, but, on the contrary, fanging is not so common with sewage manure as when animal manure has been used. *E. T. Ellis.*

PRECOCIOUS PLANTS AT ALDENHAM.

I HAVE just returned from a visit of a few hours to Aldenham, and in spite of heavy showers, a cold north wind, and sodden soil, many things were looking very bright and pretty there.

All plant life is in an unnaturally forward state for the time of year, and by no means in the dormant condition which ought to be prevailing; it is bound to experience a heavy setback and unpleasant reverse of fortune before many days have passed. I noticed Ribes speciosum, a sheet of tender green; almost all the buds had opened and were disclosing half-developed leaves the size of a threepenny-bit. The Winter Aconite was already showing splashes of vivid yellow here and there under the trees, a pleasant sight which I never remember to have enjoyed before until the New Year was well begun.

A large mass of the Sweet Coltsfoot, Tussilago fragrans, growing among a lot of old tree stumps, gratified the eye with its pale lilac colouring, and even more the nose, by its delicious Heliotrope-like smell. I noticed, too, Hamamelis vernalis and several other Wych-Hazels covered with their pink, brown and gold rosettes of flower, which twinkled in the occasional sunbeams on their bare twigs. On the bushes of Cotoneaster Simonsii hundreds of scarlet berries still showed gaily, the birds having kindly spared them.

However, perhaps the prettiest thing to be seen in the garden was a good-sized bush, about 5 feet high, of Lonicera Standishii lanceolata, one of Wilson's introductions from China.

This was covered with white blossoms, some fully and some half open, but all sufficiently advanced to develop completely if gathered and brought into a warm room. Although the shrubby Honeysuckles are not so valuable here as they are in the United States, where they can be counted upon to produce annually a full crop of showy red fruits, yet it surprises me that the better kinds are not more often to be seen in English gardens, especially when it is considered that they are perfectly hardy, accommodating as to almost any kind of soil, tolerant of the smoky atmosphere of big cities, easy to reproduce, quick-growing, and inexpensive. Surely there are not so many shrubs that will supply a pretty nosegay in midwinter that one can afford to neglect them. *Vicary Gibbs.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Austrian Briar Hybrids.—I protest against the term Austrian Briar hybrids being given to the "Pernetiana" Roses. Mons. Pernet Ducher, the raiser of Soleil d'Or, has worthily earned the honour of having his name bestowed upon a group of Roses that owes its origin to the offspring of Soleil d'Or, and the National Rose Society has adopted the name "Pernetiana." The writer of the Notes on Some of the Newer Roses in *Gard. Chron.* used the name Austrian Briar hybrids, and some few nurserymen still call these Roses by that term. To Mons. Pernet Ducher, who has lost two gallant and clever sons in the war, we owe a large debt of gratitude for his many wonderful creations in new Roses. *Walter Easlea, Eastwood, Leigh-on-Sea.*

The Loss of the Clematis in Gardens (see p. 253, Vol. LXIV.).—Mr. Robinson should do us the honour of reading our remarks before replying to them. We stated that our plants, raised from cuttings, were so badly affected by "dying back," that we had to give up this method of propagation. We are now told that we write as if this serious problem did not exist! The statement that we object to is that this disease is due to grafting. If it can be substantiated, we are quite open to conviction; if not, we suggest it should be withdrawn. *George Bunyard and Co., Ltd., Royal Nurseries, Maidstone.*

Fruit Trees in Shrubbery Borders.—Trees growing in association with shrubs need manuring somewhat more liberally than those grown in ordinary conditions. After the shrubbery has been cleaned give the fruit trees a liberal top-dressing of rich material. See that the shrubs, if over-exuberant, are not overgrowing the trees. As the fruit trees are planted in conjunction with shrubs for their ornamental character they should not be pruned severely. I remember, some years back, a Dumelow's Seedling or Wellington Apple (one of the prettiest when in flower) which was not pruned. This tree, almost without exception, produced heavy crops of good fruit. The shelter afforded by a belt of shrubs will in some localities be congenial to both Pears and Plums. As such trees are, in all probability, standards, with supports, see that the latter are in a sound condition before there is a danger of damage from a heavy fall of snow or strong winds. *James Hudson, Gunnersbury House Gardens, Acton.*

Sterilisation of Leaf-Mould. — We make the best use of leaf-mould at Keele. Beech and Oak leaves are kept separate to provide material for plunging purposes, making hot-beds, and for use in various composts. I agree with *W. W.* in his remark on p. 223, Vol. LXIV., as to the need of a machine for sterilising soil. Leaf-mould here, at one time, was badly infested with eelworms. Our method of sterilising soil and leaf-mould is rather crude, but effective. Over a large wood-fire are placed galvanised iron sheets supported by roughly built walls about 2 feet high. A large quantity of leaf-mould is placed on the sheets and kept continually turned with shovels to prevent burning. In a few minutes the whole bulk is steaming, and heated through sufficiently to destroy all insect life. After this treatment the leaf-mould is wheeled under an open shed for future use. Two men can sterilise a large quantity of mould in a day. *W. J. Guise, Keele Hall Gardens, Newcastle.*

Romneya Coulteri (see pp. 227, Vol. LXIV.).—I am doubtful if Romneya Coulteri is worth growing. I have a strong plant, and last year (the first of flowering) it had only two blooms, and this year only one, ill formed, and a very belated one that came to nothing. This is not encouraging, though the plant grows at least 3 feet high and puts up a great number of strong branches. I have seen it stated somewhere that R. trichocalyx is more floriferous, but after my experience I hardly feel inclined to try it. My plant of Romneya Coulteri has had no special attention, as I am nothing but an amateur. *T. J. Hicks, Bridge Road, Maidenhead.*

Silver Leaf (see pp. 178, 210, 215, 243, Vol. LXIV.).—I have read with great interest the opinions of the various correspondents, and also the advice of the Food Production Department, in your pages on this disease. I am in agreement with much that has been written, but a few remarks call for comment. No other fungous pest has spread so rapidly amongst fruit as Silver Leaf. I am not very old, but I remember when it was comparatively rare even amongst stone fruits. Now I think it may be said truly that few trees are immune from the complaint, and I include ornamental as well as fruit trees. I have seen all stone fruit, Apples, Lilac (in a

hedge), Pears, and common Thorn affected with the complaint. The two last-named I am not so certain of, as I am writing from memory, being in hospital, where I have been for the past fourteen months recovering from wounds. I do not think that grafting has anything to do with Silver Leaf, as I am convinced from much experience amongst young trees that it starts at the root. In every case I have examined I have found, whether affected little or much, that the stock below the "union" has had a brown centre right down to the root. Also, if "working" has to do with it, how is it that stocks which are raised from seed, layers or cuttings are attacked? I think that no woody matter should be buried in the ground, or even stacked or stored near plantations. The fungus (Stereum purpureum) can be found in its purple state upon rotting wood. Like Mr. E. Molyneux, I am puzzled why it suddenly appears upon some healthy trees in plantations that were always free from the disease. Is it from some prunings which have been left about and then buried near the roots, or does part of the root decay and so start the disease? I feel certain that the safest plan is to destroy trees if they show the slightest sign of Silver Leaf, being careful to take the whole stump out. We must still either bud or graft our fruit trees, or we shall find ourselves in a terrible muddle as to varieties, besides having many fruitless trees. *L.-Cpl. W. Radford, "The Buffs," Wenyngton Ward, 2nd Northern General Hospital, Becketts Park, Leeds.*

—— I do not think it will be found that Mr. Bates (p. 243, Vol. LXIV.) is correct in his suggestion that Silver Leaf occurs only where Plum trees are growing in stiff, clay soils. I find the disease bad in trees on light land, both where the subsoil is sand and where it is clay, but I must acknowledge that in each case the subsoil is very wet in winter. As for the age at which trees are attacked, I have no record of the disease appearing on any younger than eight years from planting. It is quite likely that the silvering of the leaves does not occur until some years after the fungus has gained access to the tissues of the branch or stem. With Mr. Hayward's opinion, that the tree must be attacked at or below the ground level, I cannot agree. The silvering may often be noticed at the end of a branch only, and the disease may be traced down through the wood until healthy tissue is reached. I cannot see that there is any escape from the accepted theory that it is a wound parasite (like canker), due to the fungus Stereum purpureum. As to the suggestion that grafted trees are more liable to the disease than those on their own roots, I think this is quite likely to prove correct, because the junction between scion and stock forms a wound through which the fungus can enter. Moreover, I have often seen Silver Leaf on Apple trees that have been top-grafted, but never on other Apple trees, which seems to be good evidence that the fungus entered by the wound made in grafting, and had nothing to do with the roots. With regard to Plums, I have seen it stated by a well-known nurseryman that trees on the Myrobalan stock are more liable to the disease than those on St. Julien. Can any correspondents confirm this? *Market Grower.*

American Blight (see pp. 50, 77, 92, 142, 180, 210, 220, Vol. LXIV.).—Some 15 years ago we were very badly troubled with American Blight, especially on Apples King of the Pippins and Ribston Pippin. They were standard trees about 40 years old, and trunk and branches were simply white with American Blight. I grafted the tree of King of the Pippins with Golden Noble on the extension system, just the main branches, leaving all the smaller branches of the Pippin variety remaining. The result is most gratifying, for it has put new life into the trees. We have had excellent crops of Golden Noble and King of the Pippins this year. We had about 2 cwt. of Golden Noble and 1 cwt. of King of the Pippins, and, what is more, the American Blight has entirely disappeared, and without spraying. We have grafted many of our old trees that had become weak in constitution by continuous bearing, with Bramley's Seedling mostly, and Golden Noble. Newton Wonder has also done well, but has not grown quite so strongly as the other two varieties. We graft all on the small branches, putting as many as 200 grafts on the large trees, then, in about four years, we have a full bearing tree. We grafted an old Ribston with Bramley's Seedling, and it is now the healthiest tree we have. In 1917 this tree bore 7 cwt. of fine, clean fruit, and in 1918 about 3½ cwt. of very fine fruit. Much might be done to improve old orchards by regrafting with these strong-growing varieties on the extension system, and all our best fruits are obtained from trees thus treated. The varieties I have found to do best are Bramley's Seedling, Golden Noble (the two best), Newton Wonder, Hector Macdonald, and Lady Henniker. I have tried many other varieties, but not with such good results as the above. They succeed for a few years and then die off, and sometimes the old trees die outright. The above varieties I have found immune from American Blight. *James Harris, Blackpill Nurseries, Swansea.*

SOCIETIES.

WINDSOR, ETON, AND DISTRICT HORTICULTURAL.

THE annual general meeting of this Society was held on Wednesday, the 11th ult., at the Town Hall, the Rev. H. Tower (chairman of the committee) presiding.

The hon. treasurer, Mr. E. J. H. Rice, submitted the balance-sheet for 1918, which showed receipts amounting to £136 10s. 6d., made up as follows: Balance in hand from 1917, £72 13s. 7d.; subscriptions, £60 17s.; dividends, Leeds three per cent. stock, £2 3s. 6d.; ditto five per cent. National War Bonds, 16s. 5d. The payments included: Purchase of National five per cent. War Bonds, £50; donation to Windsor, Eton and District Horticultural Show, £25; balance in hand, £56 9s. 4d. Mr. Rice said he thought it was a source of satisfaction to the supporters of the Society that they had been enabled to subscribe £25 for the increased production of food in Windsor and District, as shown by the wonderfully successful show held at the Albert Institute in the autumn.

On the proposition of Mr. Romaine, seconded by Colonel Jackson, it was decided to alter the rule as to the number of committee men. It now stood at 20, and he proposed it be enlarged to 25. This was carried.

The names of Mr. C. Frail and the Rev. F. G. A. Phillips (Vicar of Taplow) were then added to the committee.

Mr. Ward Frost wrote resigning his position as assistant hon. secretary of the Society, owing to want of time to carry out the duties, and it was accepted with regret.

On the proposition of Colonel Jackson, seconded by Mr. Cowley, the president (Canon Sheppard), hon. treasurer (Mr. E. J. H. Rice), the hon. secretary (Rev. L. G. Reed) and the committee were unanimously re-elected.

The Rev. M. F. Foxell was elected assist. hon. secretary.

The Society will hold a show on Saturday, June 28, 1919, and it was decided that the assistant hon. secretary should write to Canon Sheppard asking him to approach the King, with a view to obtaining permission for the show to be held in the Slopes of Windsor Castle.

ROYAL HORTICULTURAL OF IRELAND.

THE eighty-ninth annual general meeting of the Royal Horticultural Society of Ireland was held on the 17th ult. at 5, Molesworth Street, Dublin, for the purpose of receiving the report and statement of accounts for the year ending December 1, 1918.

Sir John Ross of Bladensburg presided.

Letters of regret for absence were received from the Marquis of Headfort, president of the Society, Viscount Powerscourt, Lord Frederick FitzGerald, and Mr. D. L. Ramsay.

In the report of the Council it was stated that two successful exhibitions were held during the year. Owing to the support given to the Society by the officers and men of the Grand Fleet, by presenting valuable prizes in recognition of work done by the Irish branch of the Vegetable Products Committee, under its auspices, the Council considered the advisability of extending the originally proposed private winter show into a two days' public exhibition, the results of which fully justified the alteration. The Winter Show also was a notable success. The work of the Irish branch of the Vegetable Products Committee, for the sailors, commenced four years ago, had, thanks to the support of the public, been consistently maintained, and there was still urgent need for this good work, for a few months more.

Sir Frederick Moore, hon. secretary, said that the report was satisfactory, inasmuch as the Society was in debt to the extent only of £33 17s. 6d.

The chairman, moving the adoption of the report, said that nearly all societies of this kind had suffered during the war, but, now that the war was over, they should exert themselves to recover lost ground. It was a pleasure to be able to allude to the work done by the Vegetable Products Committee in providing fruit and fresh vegetables for the gallant men of our Navy. One thousand tons of fruit and vegetables had been sent by the Committee during the four years. Their president had given the Society good advice when he suggested that they should turn their attention to forestry, and he had no doubt that it would be taken up energetically, for there was much need of growing timber in Ireland.

Mr. D'Olier seconded, and the report was adopted.

On the motion of the chairman, seconded by Mr. Miley, it was resolved to instruct the Council to incorporate in the title of the Society the word "Arboricultural."

The members of the Council were re-elected, Mr. James Toner being added.

Obituary.

M. Roe.—We regret to record the death of Mr. M. Roe, late bailiff and fruit manager for Capt. Owen Croft, Pomona Farm, Withington, Hereford. Mr. Roe passed away on the 21st ult., after a month's illness; he leaves a wife and young family.

James Besant.—Many gardeners, especially in Scotland, will learn with regret of the death of Mr. James Besant. Born in Hampshire, he went to Scotland at an early age, and began his professional career in the nurseries of Messrs. D. Stewart and Sons, Broughty Ferry. After serving in several local gardens for a number of years, including four years at Rossie Priory under the late Mr. Doig, he was appointed gardener at Mylnefield, where he remained for ten years before he went to occupy a similar position at Castle Huntly, Longforgan, in which place he remained about 30 years. Mr. Besant was a most successful exhibitor at horticultural exhibitions, and particularly at Dundee and Edinburgh. While he was an enthusiastic and successful cultivator of Chrysanthemums, he scored his greatest successes with indoor fruit, notably Grapes. He won the £50 Challenge Cup offered for Grapes at the Edinburgh International Show, while for the same exhibit he was awarded the King's Cup, the R.H.S. Medal and £15, also on the same day the first prize—a silver tea service—for six bunches of Grapes, no mean achievement. For five years in succession he won the first prize for the best collection of orchard house fruits at Edinburgh. Retiring in the spring of 1914 he returned to England to be near some of his family. Three of his sons followed gardening: James is head gardener to Lord Hastings at Melton Constable; William, head gardener to Mr. Craig Sellars, Ardtornish Towers, Morvern; and John, an old Kewite, is foreman of the outdoor department in the Royal Botanic Gardens, Glasnevin. His daughter, who took the M.A. degree at Dundee University, was for a time Assistant Registrar to the British Legation at Berne. To his widow and family the sincerest sympathy of many old friends will be extended. *Jas. Whitton.*

CROPS AND STOCK ON THE HOME FARM.

THE FUTURE OF FARMING.

As so many changes have come over the whole industry of farming, consequent upon the war, the prospect of success on a farm of any pretensions to size is none too rosy. At present, the selling of Wheat at the maximum price is not easy; millers hold large stocks, and are not keen to buy, except at a reduced figure. The farmer may be requiring money or straw, therefore he meets with difficulty in two ways. During the early threshing season, with continual wet weather and a shortage of threshing machines, farmers experienced much difficulty in getting their seed corn ready in time for sowing, apart from any question of selling corn to others. Further, the plague of rats and mice is all against keeping cereals in the ricks, where in normal conditions it keeps better than in bulk, no matter how suitable the store places are. Grain in bulk requires repeated turning to prevent it becoming musty; this means labour.

The Government has fixed the price of all grain up to June 1, allowing only 1s. advance per quarter from October 1 last; such a sum is not likely to encourage the retention of cereals at the risk of distinct loss. Farmers should thresh the bulk of their corn and turn it into cash.

The whole success of farming hinges upon future prices; if these are maintained as now, in all spheres, the farmer will be content, and will gladly pay the increased wages and augmented cake and manure bills. He can then reasonably demand a good day's work for the wages paid. I regret to say there does not appear to be any tendency to over-exertion amongst employees, and farmers will do well to adopt further systems of piecework.

I fear extra smart farming will not predominate in the near future, as time will not admit of so much clearing up as many of us have practised in the past. The arable and cattle farmer on a large area will be compelled to drop many of the side lines of culture, such as Onions, Carrots, Cabbages, Mangold, Sugar Beet, Sunflowers, and edible Peas, and must reduce his crop of Potatos under certain conditions.

The making of butter, too, is one of the doubtful assets of the future. At the present time a loss of eighteenpence is incurred on every pound of butter made, apart from the labour in storing and preparing the cream and making it into butter. Two gallons of milk are required for 1 lb. of butter; at a low price the milk is worth 4s., while the maximum price of butter is 2s. 6d per lb. for all grades. I think it will be admitted that best butter is worth more than double the price paid for poor butter, but there is no difference in the control price. No one can truly say the butter industry receives encouragement from the authorities.

The up-to-date farmer must put all his energy into improved methods of farming. He must cultivate the land thoroughly well and use motor ploughs, self binders, and grass cutters. With a good type of a motor-driven plough six acres per day can easily be ploughed on ordinary light land—equal to the work of fourteen horses. In harvest work, too, much may be done with machinery; an 8-foot self-binder drawn by a tractor will quickly clear acres of standing corn. With about 600 acres of arable land, a threshing machine driven with the motor is a profitable investment, and pays for its cost in three years at the present price of hire for threshing.

The increased use of artificial manures must follow now that it is known how much their discriminate use adds to the crop yields. Oats and Barley can easily be grown successively on the same land, which facilitates cropping. With the extensive ploughing up of poor grass land in the past and the probable further reduction of such pastures, the remaining grass will need to be further enriched to provide the hay and feeding space for an increase of cattle, which all should encourage.

Some farmers regret the reduction of the grass area. I do not, because land that only produces half a ton of hay per acre is not "doing its bit." The ploughing up of such plots need not limit to a serious extent the supply of hay, because from improved arable culture and the excellent grass and Clover seeds obtainable much heavier crops of hay of better quality can be secured in quite a short period. Clover, Sainfoin, and mixtures of grasses arranged on the various methods of seeding produce the best of hay, especially for horses. Meadow hay is more valuable for dairy cows, but there is less bulk.

On no part of a farm can such rapid improvement be seen as in pasture fields when a practical system of manuring is followed, especially on hilly down land, which has in the past been regarded as more or less derelict land. Too little attention is paid to the draining of wet pastures, but many would not need draining if the natural watercourses and ditches were kept free. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

TRADE NOTES.

THE annual meeting of the British Florists' Federation will be held at Essex Hall, Strand, W.C., on Thursday, January 23, at 2.30 p.m.

THE British Florists' Federation and the National Chrysanthemum Society have decided to attach themselves to the Chamber of Horticulture.

COVENT GARDEN FLOWER MARKET was closed on Boxing Day, to the delight of very many growers and salesmen. Now that a precedent has been created it is hoped the Flower Market will always be closed on Christmas and Boxing Days. A few sale-rooms around the market were opened for an hour or two on December 26 to allow of the disposal of a small consignment of French flowers.

REMOVAL OF CONTROL OF RAFFIA.

MR. CHAS. H. CURTIS, the secretary of the British Florists' Federation, received the following letter from Dr. F. W. Keeble, of the Food Production Department, under date of December 31, 1918: "In further reference to your letter of November 14 regarding the release of Raffia, I have to inform you that the Raffia (Control) Notice, January, 1917, and the Raffia (Prices) Order, July, 1917, have been cancelled. The position, however, has not changed greatly for the better, although in the near future it may be expected that the usual wholesale houses will be importing from Madagascar. Now that the Order in question has been rescinded, there should be no difficulty in securing by next May, or perhaps earlier, an adequate supply of Raffia, and I hope that it may not be impossible to obtain the release of the small military supply. This matter is receiving attention."

PROHIBITION OF PLANT IMPORTS INTO AMERICA.

MR. R. WYNNE, secretary of the Chamber of Horticulture, writes: "I beg to inform you that I have received a copy of a General Notice issued by the American Horticultural Trade, and addressed to the Foreign Horticultural Trade and Allied Branches. This notice states that the Department of Agriculture approved on November 18 the drastic proposals of the Federal Horticultural Board to exclude importations from all foreign countries of plants, with the exception of such as are required for propagating purposes in the States. Bulbs and bulbous roots, with some small exceptions, are also excluded.

"As this matter will be prejudicial to trade interests in this country, I have considered it expedient to call an early meeting of the Committee of this Chamber to consider it fully, and in the meantime I shall be very glad to receive the views of any of your readers who may consider it vital for steps to be taken for their benefit. I am also placing myself in communication with the Foreign Office and the American Embassy, to ensure obtaining the latest official information on so important a subject."

DEBATING SOCIETIES.

READING GARDENERS'. — "The Culture of Tomatos under Glass" was the subject arranged for discussion at the fortnightly meeting of the above association held in the Recreation Room, Abbey Hall, on Monday evening, December 9, 1918. This was introduced by Mr. W. Chislett, The Gardens, Bill Hill, Wokingham. Mr. H. C. Loader, The Gardens, Erlegh Park, exhibited fruits of Sutton's Princess of Wales Tomatos. Mr. G. Tovey, The Gardens, Leighton Park, was awarded the association's Award of Merit for a specimen plant of Chrysanthemum.

LAW NOTE.

ILLEGAL USE OF WHEAT.

AT Thorpe, Essex, a lady farmer of Great Holland, near Clacton, was recently fined £227 for using Wheat for poultry feeding. It was stated that defendant had disregarded repeated warnings, saying she would obey the laws of God, but not of man.

GARDENING APPOINTMENTS.

Mr. W. Wood, for more than 6 years Gardener to Major HAWKSWORTH SMYTH, Ballynegall, Mullingar, as Gardener to MAYNARD SINTON, Esq., Ballyards House, Armagh.

Mr. F. Bailey, as Gardener to Sir GUY SEBRIGHT, Beechwood, Dunstable, Bedfordshire.

Mr E. Mathews, as Gardener to Sir ERNEST CASSEL, Moulton Paddocks, Newmarket, Cambridgeshire.

R. Onslow, for 12 years at Dogmersfield Park Gardens, Winchfield, Hants, as Head Gardener to J. L. WADDILOVE, Esq., The Elms, Spaniards Road, Hampstead.

Mr. A. Matthews, for 10 years Gardener at Everley Manor, Marlborough, as Gardener to Capt. A. S. WILLS, Thornby Hall, Northampton. (Thanks for 2s. 6d. for R. G. O. F. Box.—EDS.)

Mr. C. Ridler Dutton, for the past seven years Gardener-Bailiff to C. S. CLARKE Esq., Tracy Park, Wick, near Bristol, as Gardener-Bailiff to Lieut.-Col. CAPEL, The Grove, near Stroud, Gloucestershire.

Mr. E. Matthews, for the past 3½ years Gardener to His Grace the Duke of WELLINGTON, K.G., Stratfieldsaye, Mortimer, as Gardener to the Right Hon. Sir ERNEST CASSEL, Moulton Paddocks, Newmarket.

CATALOGUES RECEIVED.

SEEDS.

DICKSON & ROBINSON, Manchester.
JOHN PEED & SON, West Norwood, London
GEORGE FAIRBAIRN & SONS, English Street, Carlisle.
STEWART & Co., 13, South Street, Andrew Street, Edinburgh.
LITTLE & BALLANTYNE, Carlisle.

SLUIS & GROOT, Enkhuizen, Holland.—Flower seeds.

ANSWERS TO CORRESPONDENTS.

FRUIT TREES AND TENANTS: *J. P.* Unless an agreement exists to the contrary a tenant is not permitted to remove any standard, bush or cordon fruit trees from his landlord's property on giving up his tenancy, even though he has planted them himself.

GARDENERS' WAGES: *G. P.* Considering the accommodation, we think the weekly wages for such a position as you suggest should be not less than 35s. or 40s.

HYBRIDS OF CITRUS TRIFOLIATA: *J. C.* We hope to be able to obtain the information required in a few days and to send it you by post.

LAVENDER CULTIVATION: *L. M. B.* Lavender grows well in deep, well-drained soil, rather light in texture but fairly rich. Planting should be deferred until early spring, and if year-old plants, i.e., those rooted as cuttings late in 1917, can be obtained, a good start may be made. The position you have in view should prove suitable. Rosemary should succeed under the same conditions. The price of dried Lavender per pound can be obtained from a wholesale chemist, perfumier, or fancy-soap manufacturer; it varies with the season and the quality of the produce.

PIG MANURE: *S. T.* Pig manure is quite suitable as a fertiliser, especially for light soils. On heavy, moist land it should not be used until partly decomposed, as it is wet in a fresh state and would tend to make heavy land cold and moist. Drainings from pigsties are suitable for established fruit trees, and during the winter may be poured on the soil occupied by the roots of the trees.

REPORT OF ORMSKIRK POTATO TRIALS: *W. M. S.* As the Potato trials held at Ormskirk in 1918 were conducted partly under the auspices of the Board of Agriculture it is probable that body will issue the report. Mr. J. Snell had charge of the trials for the Board of Agriculture and the Ormskirk Potato Society.

Mimosa, per pad ...	18 0-21 0	Roses, Safrano, per packet .	2 6- 3 6

REMARKS.—Since the market closed on Christmas Eve only small consignments have reached the salesmen up to this morning. Many growers have doubtless practically cleared their stocks of Chrysanthemums, Carnations and Roses for the Christmas trade. Business appeared to be more brisk on Saturday last for the New Year's festivities. Single Daffodils, Scarlet Carnations, and Violets were principally in demand. Consignments of Daffodils and Yellow and White Narcissus are arriving from the West of England. The consignments of cut flowers from the Channel Islands are becoming more plentiful and consist of Yellow and White Narcissi, a few scarlet Anemones, single Violets, Freesias, and Smilax. The consignments of French flowers are very irregular, and mostly consist of paper-white Narcissus and Soleil d'Or; a few pink Anemones, Ranunculus, and white Narcissi have arrived in excellent condition during the past week. There is also a good supply of Lily of the Valley and Roman Hyacinths.

Fruit: Average Wholesale Prices.

Horseradish, per bun.	2 6- 4 0	Watercress, per doz	0 10- 1 0

REMARKS.—Supplies of black Grapes are equal to the demand, but the crops of Muscat varieties are finishing. There are some fine samples of Almeria Grapes on offer. Nuts are very scarce. Forced vegetables now obtainable consist of the following:—Dwarf Beans, Mushrooms, New Potatos, Asparagus, and Seakale. Forced Rhubarb is also available. Winter Greens and roots from out-of-doors are all plentiful. Cucumbers are a limited quantity. A few Tomatos are being sent by growers. *E. H. R., Covent Garden Market, January 1, 1919.*

THE CELEBRATED XL ALL SPECIALITIES. BEEN ON TOP FOR 25 YEARS AND STILL THERE!—XL ALL CAUSTIC WINTER WASH (in powder). 1lb. tin makes 8 to 12 gallons. It thoroughly cleanses Fruit Trees and Bushes, both buds and bark. Can be used any time before the buds begin to swell in the spring. XL ALL NICOTINE LIQUID INSECTICIDE. The gardeners' favourite Wash for the absolute destruction of Thrip, Scale, Mealy Bug, &c. If this wash is used occasionally, a total absence of insects, both on Fruit Trees and Plants, can be secured in any garden. XL ALL NICOTINE SHREDS. The most potent, safe, and effectual Fumigant. Used without any apparatus, simply burn on the floor of the Greenhouse. XL NICOTINE FUMIGATING COMPOUND. Both in liquid and cake, these old favourites are still as popular as ever. Many other XL ALL Preparations are indispensable in the garden. Get a complete list from your N.S. or Florist, or send to me for one and name address of your nearest Agent.—G. H. RICHARDS, Manufacturer, 234, Borough High Street, London, S.E. 1.

PLANTS, &c., WANTED.

WANTED, 1,000 large ASPIDISTRAS, old plants, suitable for stock; cash or exchange. See other advertisements; catalogues free. — SMITH, London Fern Nursery, Loughborough Junction, London, S.W. 9.

WANTED, for a small holding, Narcissus Tulips, any sort of bulbs, Fruit Trees, also Currants, Gooseberries, Strawberries, Fowls, Ducks, Geese. —Description and price to WESTON, Manor Farm, Wolvercote, Oxford.

PLANTS, &c., FOR SALE.

JEFFERIES' HYBRID GLADIOLI. English raised and English grown. For massing, few flowers can equal the magnificent display made by our beautiful Hybrid Gladioli, during the months of July, August, and September. Our strain the result of careful hybridising, is altogether superior to the ordinary mixture, usually of Continental origin, offered by the trade. The flowers vary in colour, from pure white, through shades of lemon, yellow, orange, salmon, to deep blood red and purple, the pleasing art shades of orange and salmon predominating.

Secure your bulbs at once; they are scarce, and will be difficult to procure later on.

Strong flowering bulbs, per 100 17s. 6d., per 1,000 £8, carriage free for cash with order.

JOHN JEFFERIES & SON, LTD.,
Royal Nurseries, Cirencester.

SPECIAL OFFER.

FOR IMMEDIATE DISPOSAL.

A LARGE TRADE STOCK of ESTABLISHED ORCHIDS, comprising

50 ONCIDIUM ROGERSII, 30s. per dozen.

250 CYPRIPEDIUMS, superior decorative types, hybrids of Leeanum, &c., very good plants, in variety, 42s. per dozen.

100 ODONTOGLOSSUM GRANDE, smart plants, in two sizes, 30s. and 60s. per dozen.

300 CATTLEYA GASKELLIANA, fine plants, in 6in. pots, 2 and 3 leads each, 60s. per dozen.

300 CATTLEYA and LAELIO-CATTLEYAS, HYBRIDS, good plants and useful decorative varieties, in 6in. pots, 48s. per dozen.

500 CATTLEYA and LAELIO-CATTLEYA SEEDLINGS (unflowered), of very choice parentage, purchased from the "Brackenhurst" collection, nice sound plants, mostly in 2in. pots, 20s. per dozen.

2,000 ODONTOGLOSSUM CRISPUM, smart plants, in 4in. and 5in. pots, £12 per 100.

2,000 ODONTOGLOSSUM CRISPUM, nice plants, in 3in. pots, £6 per 100.

5,000 ODONTOGLOSSUM CRISPUM, small plants, healthy and sound, many unflowered, 50s. per 100.

These Od. Crispum are the best type, the famous and beautiful Od. Crispum "Solum," and Od. Crispum "Queen Empress," and others having originated from this stock.

The above is a specially cheap offer, as the plants must be cleared immediately, thus affording a most favourable opportunity to buyers desirous of replenishing stocks, as no importations from abroad are likely to arrive for some time.

Specially favourable terms to large buyers.

Full particulars from and all inquiries to

A. J. KEELING & SONS,
Westgate Hill, Bradford.

SCARLET OAKS, grand colour, 5 to 7 feet, 60s. per 100.—HINTON BROS., Nurserymen, &c., Warwick.

"PESTITE" kills wireworms, rookworms, cockchafer grubs, Julus worms, and other soil pests; also "club root" and other fungoid diseases. Price: 28lbs. 5s. 6d., 56lbs. 7s. 6d., 112lbs. 10. 6d., 1 ton £8, all carriage paid, from G. LANG & SONS, LTD., Hounslow, Middlesex.

WEEDS! WEEDS! WEEDS! Now is the time to destroy them before casting their seeds. If your paths are cleared now they will remain clean for the best part of next year. Our Weed Killer is safe to handle, non-poisonous, will not harm birds or animals, is a powder; only requires sprinkling on the weeds.

1 cwt. sacks, 20s., free on rail, London.

CLEVELAND & CO., 12, Gt. Queen St., Kingsway, W.C.

BANSTEAD or WALTON HEATH LOAM.—A splendid soil for all purposes; fresh cut or rotted.—Particulars of YOUNG BROS., Betchworth, Surrey.

SITUATIONS VACANT.

Twenty words (or three lines including headline) 3s., and 6d. for every succeeding eight words (or line) or portion thereof. Fee for having replies addressed to this office, 6d.

Gardeners desiring their Advertisements repeated *must give full particulars, otherwise no notice will be taken of their communications. Name and address alone are insufficient.*

Gardeners writing to Advertisers of Vacant Situations are recommended to send them **copies** *of testimonials only, retaining the originals. On no account should they enter into communication with unknown correspondents who require a fee beforehand.*

Advertisers are cautioned against having Letters addressed to Initials at Post-offices, as all Letters so addressed are opened by the Postal Authorities and returned to the Sender.

PRIVATE.

WANTED, by the Village Centres Council for their estate at Andover, established for the training of disabled men, an active, capable, and qualified MAN, to take charge of the Horticultural and Agricultural Department; must be well up in scientific and practical work, and capable of economically managing the estate and of imparting knowledge to the patients by lectures and demonstrations, &c.; a good salary paid to a suitable man, with a house.—Apply, giving full particulars of qualifications, salary expected, and references, to MR. JOS. CHEAL, Chairman of the Horticultural Committee, The Nurseries, Crawley, Sussex.

GORDON BOYS' HOME, WOKING.

WANTED, HEAD GARDEN INSTRUCTOR; £105, rising to £115, plus £15 for evening work, together with house, fuel, and uniform.—Apply in writing to THE GOVERNOR.

WANTED, at once, an all-round HEAD WORKING GARDENER, where one other is kept; no cottage.—235, Willesden Lane, N.W.

WANTED (near Hitchin), HEAD WORKING GARDENER; man and boy kept; wages £2 weekly; good house.—Apply, H., Box 11, 41, Wellington Street, Covent Garden, W.C. 2.

HEAD WORKING GARDENER of two wanted. — Apply by letter to MRS. MICHELL, Crakehall Hall, Bedale, Yorkshire.

WANTED, experienced HEAD WORKING GARDENER for large town Garden, with Vinery and Tropical Plants; lodge provided; wages 38s. weekly. — Address by letter, DR. HURRY, Westfield, Reading.

WORKING HEAD GARDENER wanted immediately; experienced all-round man; Vines and Peaches a speciality.—Write wages expected, references, to CAPTAIN HOGGARTH, Mia Hall, Dyserth, North Wales.

WANTED, HEAD WORKING GARDENER; two under normally; only one at present; wages 35s., cottage, coal, light; good reference essential.—MAJOR J. W. BURNS, Leesthorpe Hall, Melton Mowbray.

WANTED, HEAD WORKING GARDENER for London; under man and boy kept; all-round experience, no quarters.—Write, stating wages, experience, &c., to G. L. F., Alderton, Stanmore, Middlesex.

GARDENER wanted; SINGLE-HANDED; extra help when required; good all-round experience; middle age; no family; highest references; able to milk; comfortable cottage and vegetables, &c. Wages £2.—Apply, H. GREEN, Warfield Dale, Warfield, near Bracknell, Berks.

GOOD SINGLE-HANDED GARDENER wanted; must be experienced in Glass, Flowers, and Vegetables; good wages and cottage.—Write, in first instance, to GEORGE HERBERT, Duck's Hill Nursery, Northwood, Middlesex.

GARDENER (SINGLE-HANDED) wanted; married; two good rooms, wash-house, &c.; poultry; good wages.—E. K. CHAMBERS, The Lodge, Pinner, Middlesex.

WANTED, a SINGLE-HANDED GARDENER; experienced in all branches.—Apply, The Hollies, Elphinstone Road, Hastings.

WANTED, WORKING GARDENER, to take charge; one kept; Fruit, Vegetables, and General; for factory Garden and grounds; must be experienced.—Write, stating full particulars and wages, TURNER'S COCOA WORKS, Wallington, Surrey.

GARDENER wanted; married man; thoroughly experienced in Herbaceous and Hardy Plants, Lawns, &c.; wages 32s. to 35s.; cottage and garden found.—Apply, with references and experience, to HEAD GARDENER, Wittington, Marlow.

GARDENER wanted, for Herbaceous and Hardy Plants, Lawns, &c.; no Glass or Vegetables; wages 30s. to 35s., with good cottage and garden.—Apply, with references or experience, to J. DOUGLAS WATSON, Warley Lodge, Little Warley, Essex.

WANTED, experienced GARDENER for small private Garden in London; if a married man wife can work as housemaid; references required. State age, experience, and salary.—Reply, M., Box 10, 41, Wellington Street, Covent Garden, W.C. 2.

WANTED, experienced WORKING GARDENER; Oxfordshire village (2 miles from Bicester); cottage. State age, wages, experience, references, &c.—BAKER, Chesterton, Bicester.

WANTED, experienced GARDENER; Indoor and Outdoor work.—Apply, with references, to MR. E. M. HANN, The Rise, Llanishen, near Cardiff.

GARDENER wanted at once for gentleman's Garden; active, strong; age about 30-35; chiefly for Kitchen Garden and Grounds at present, but knowledge of all Garden work necessary; Church of England; married; state age, experience, and all particulars; gentleman's recommendation preferred; two other men working with him; cottage given.—Apply, MRS. TEESDALE, Whitminster House, Whitminster, near Stonehouse, Gloucestershire.

WANTED, a thoroughly experienced all-round GARDENER; cottage and garden provided. —W. HOWARD-FLANDERS, Latchingdon, Essex.

WANTED, active WORKING GARDENER, who knows his job, and is capable of making large Garden pay; good wages; considerate treatment; interest in results.—Send full particulars as to age, experience, capabilities, &c., to COUNCILLOR J. W. EASON, J.P., Scartho House, Grimsby.

WANTED, good WORKING GARDENER, with a boy under him; wages 35s. and a good cottage.—Apply, J. RIPLEY, Ampney Crucis, Cirencester, Glos.

WANTED, WORKING GARDENER; Flower, Vegetable, Tennis Lawn; single; if married no children, wife employed house; good home and wages; rooms and board found.—KIRK, St. Catherine's End, Ruislip.

WANTED, GARDENER; all-round knowledge; small Garden, little Glass; help given; good lodge; suit married couple.—Apply, stating wages and experience (good references essential), WARDEN, Wessex Hall, Reading.

WANTED, experienced KITCHEN GARDENER; also three MEN for Pleasure Grounds; Alpines and Herbaceous Borders.—Apply to A. ROBBINS, Canons, Edgware, Middlesex.

WANTED, near Chester, experienced TOMATO GROWER and GARDENER.—8, Burford Avenue, Whalley Range, Manchester.

WANTED, GARDENER, for Pleasure Ground and Kitchen Garden; several others kept; £2 per week; permanent place to suitable man.—Apply, HEAD GARDENER, "Heathlands," Parkside, Wimbledon Common, S.W.

WANTED, MAN, for Lawns and Pleasure Grounds; also two MEN for General Garden work; good cottages on estate.—Apply, stating wages, to HEAD GARDENER, Trosley Towers, Wrotham, Kent.

WANTED, a good MAN, for Lawns, &c., take turn with duty; Bothy, coals, vegetables.—Apply, with full particulars, to HEAD GARDENER, Nonsuch Park, Cheam, Surrey.

WANTED, SECOND GARDENER; must have good knowledge, both Inside and Out; would have to take his turn; either married or single man would do; cottage on estate for suitable married man.—Write, stating experience, &c., together with copies of references and wages required, to A. E. LLOYD, Manor House, Woodmansterne, Surrey.

WANTED, SECOND GARDENER, for Pleasure Grounds and Kitchen Garden; cottage provided.—Write, stating experience, age, family, together with copies of references and wages required, E. A. CHETTLE, Brackenber Lodge, Sunningdale, Berks.

WANTED, at once, SECOND GARDENER, where several are kept; principally Inside.—Apply, stating wages, with references, to J. G. WATTS, Stargroves Gardens, East Woodhay, Newbury.

UNDER GARDENER as SECOND; Inside and Out, with good knowledge of both.—Write, stating experience, with copies of references and wages, to HEAD GARDENER, Parkfield Kenilworth, Warwickshire.

WANTED, UNDER GARDENER, second of six; must be experienced; Inside and Out. State wages, references, &c. Also JOURNEYMAN, for Outside. Preference given to Army discharge.—COPEMAN, Cliveden, Shenfield, Essex.

UNDER GARDENER required on Hampshire estate; good wages to suitable man; furnished rooms or unfurnished cottage provided.—Write, W., 6, Melbury Road, Kensington, W. 14.

WANTED, UNDER GARDENER, for Glasshouses; thoroughly experienced; good wages to competent man.—Apply, H. LLOYD, Ewell Place Gardens, Surrey.

WANTED, UNDER GARDENER, principally for Inside work; cottage for suitable man. —Apply, HEAD GARDENER, Basset Wood, Southampton.

WANTED, temporary or permanent UNDER GARDENER; must understand pruning Fruit Trees and Roses; 35s. a week. — Apply, "Woldhurst," Chichester.

WANTED, Two UNDER GARDENERS, single; experienced, Inside and Out.—State wages required, with particulars, to HEAD GARDENER, Hanstead House, Bricket Wood, near St. Albans, Herts.

WANTED, immediately, experienced FOREMAN; one able to take full charge Outdoors, in good establishment, until Gardener freed from Army; permanent situation as Inside Foreman afterwards.—Full particulars to MRS. CLUTTERBUCK, Putteridge, Luton.

WANTED, GENERAL FOREMAN; must thoroughly understand Vegetable Culture; very little Glass at present. Also good OUTSIDE JOURNEYMAN wanted.—Apply, stating experience and wages required, to HEAD GARDENER, Houghton Hall, King's Lynn, Norfolk.

WANTED, experienced GENERAL FOREMAN GARDENER; married; no children or one child only.—LADY MURIEL WORTHINGTON, Maple Hayes, Lichfield.

FOREMAN or good JOURNEYMAN wanted. Full particulars of experience and wages, with Bothy, &c.—C. GARRATT, Oanwell Hall Gardens, Sutton Coldfield.

WANTED, JOURNEYMAN, for Fruit and Plant Houses.—State particulars of experience and wages to W. WARD, Canford Manor Gardens, Wimborne, Dorset.

WANTED, JOURNEYMAN; experienced in Fruit and Plant Culture, to take lead. State particulars of experience and wages, with Bothy, &c., to GARDENER, Woodhatch Gardens, Reigate, Surrey.

JOURNEYMAN wanted at once for Houses. State wages and experience. 1 p.m. Saturdays.—T. BIRKINSHAW, Caldecote Towers, Bushey Heath, Watford.

WANTED, for these Gardens, JOURNEYMEN, for both Inside and Out; discharged soldiers and sailors preferred. State experience and wages expected, with Bothy, milk, and vegetables.—Apply, FORESTER & GARDENER, Kingston Hall, Derby.

WANTED, Two JOURNEYMEN; one Inside and one Outside; good wages offered, with Bothy, milk, and vegetables; 1 o'clock Saturday; duty and overtime paid extra.—Apply, with particulars, to H. PRINCE, The Gardens, Polesden Lacey, Dorking.

TWO JOURNEYMEN wanted; Inside; good experience with Fruit and Plants. Also MAN for Lawns. Good Bothy. State wages and experience.—C. JENNINGS, Littlegreen Gardens, Petersfield, Hants.

WANTED, young MAN, 20 to 22, for Inside and Out; able to do potting, pricking off, and fires; duty alternate weeks; lodge in village.—Apply, stating experience and wages expected, COL. ORLEBAR, Hinwick House, Wellingborough.

WANTED, Two young MEN, used to Gardening; one for Inside and Out, and the other for Outside work; wages 38s. and 36s. per week, with Bothy and fire; light duty every three weeks; 1 o'clock Saturday.—Apply, GEORGE COLEMEN, The Gardens, Ynisodwyn, Ystalyfera.

POST FREE ON APPLICATION.

Horticulture and the Cessation of Hostilities

DURING the past four years gardeners' thoughts and energies have been devoted entirely to food production, with the consequence that great developments have been made in the raising of home-grown vegetables. None who have had the pleasure of sowing and gathering their own crops will in the future wish to give it up.

Now that the sterner uses of the garden are passing, owners will turn their attention once more to beautifying their homes with the old English Flowers which have been brought to such perfection, and for which the homes of England were so renowned during the long years of peace. But the reconstruction of the garden must be gradual, like all other works of reconstruction which lie before us, and we must not expect during 1919 to be able to restore our flower beds and borders to the full glory of the Spring and Summer of 1914.

Much, however, can be done by the sowing of annuals for the Summer beds, such as Asters, Stocks, Antirrhinums, Godetias, Clarkias, and others enumerated in our Catalogue. Primulas, Begonias, and Cinerarias sown this Spring will again make the greenhouse a source of interest and delight during the winter months, while Wallflowers, Polyanthus, and Pansies sown and transplanted this year will ensure a bright display in the spring of 1920.

Time, thought, and money devoted to Flower Seeds in 1919 will give no less satisfaction and even greater pleasure than was derived from the vegetable garden in the war years.

One of the beneficial results of the war will be that vast numbers will find new pleasures in life that had never before occurred to them, and one of the chief of these will be their flower and vegetable gardens.

SOME EXPERIMENTS ON GROWING MAIZE IN ENGLAND.

MANY people in this country grow a small quantity of Maize, but almost always with the object either of using it in the green state as fodder, or adding it to the resources of their vegetable produce in the form of unripe cobs. For the former purpose some tall, luxuriantly-growing variety is used, in which the cob never approaches ripeness in this country. For the latter purpose one has the choice of several of the early varieties of Sugar Maize, principally those which have lately been improved by the American raiser. But these, of course, are hardly suitable for the production of a ripe grain crop. The recent scarcity of poultry food has induced some people to attempt Maize cultivation on a small scale for the sake of the ripe grain, a purpose for which a flint or a dent Maize is required. The only variety suitable for this is Sutton's Quarantain, a dwarf form of Yellow Flint. It ripens very well, but the cob is a tiny one, and the yield is low. If a flint Maize, giving a good yield and ripening well in our climate could be evolved, it would undoubtedly be a boon to the small-holder, and possibly also to the agriculturist. Maize needs so little attention during growth, and is so easily garnered and stored, that it should make a ready appeal to the small cultivator if a suitable variety were forthcoming. Such a variety has, I believe, been found, and it is with the object of bringing it to the notice of those who are interested in the matter that I propose to give an account of some experiments that I have made at the Institute of Genetics in Cambridge during the past few years.

The possibility of growing Maize as a grain crop in this country occurred to Professor Biffen some years ago, and with this idea he made trials of some early varieties. Among these were two kinds called Gehu and Eighty-day White. Apparently they were grown closely together, so that free crossing occurred, and the mixture resulting was subsequently sown. Owing to pressure of other work Professor Biffen was unable to continue this experiment, nor at that stage did it appear very promising. I had watched this Maize growing on the Cambridge University Farm, and it struck me that it would be useful material for demonstrating Mendelian inheritance in connection with my lectures. At my request Professor Biffen very kindly gave me a few cobs in 1914. Heads ripened well in 1915, and I determined, for the sake of my fowls, to grow a larger quantity in the following year. I selected the earliest and largest cobs for this purpose, and in 1916 the yield was evidently a good deal higher than it had been the year before. The improvement was sufficiently striking to suggest that further work along the same lines might evolve a Maize that ripened well in our climate, producing at the same time a good yield. This was accordingly taken in hand, and I may now go on to give some account of the results obtained during the past two years.

On May 10, 1917, about 3½ lbs. of seed from the best of the 1916 cobs were grown on two patches measuring in all 187 square yards. The seed was sown closely in drills 2 feet apart, the amount of seed used being rather over 1½ bushel per acre. An interval of about 3 inches was allowed between each seed in order to guard against possible poor germination. As it turned out such a precaution was unnecessary, since the seeds germinated extremely well. However, the crop was not thinned, and the only attention paid it was to hoe once when the young plants were

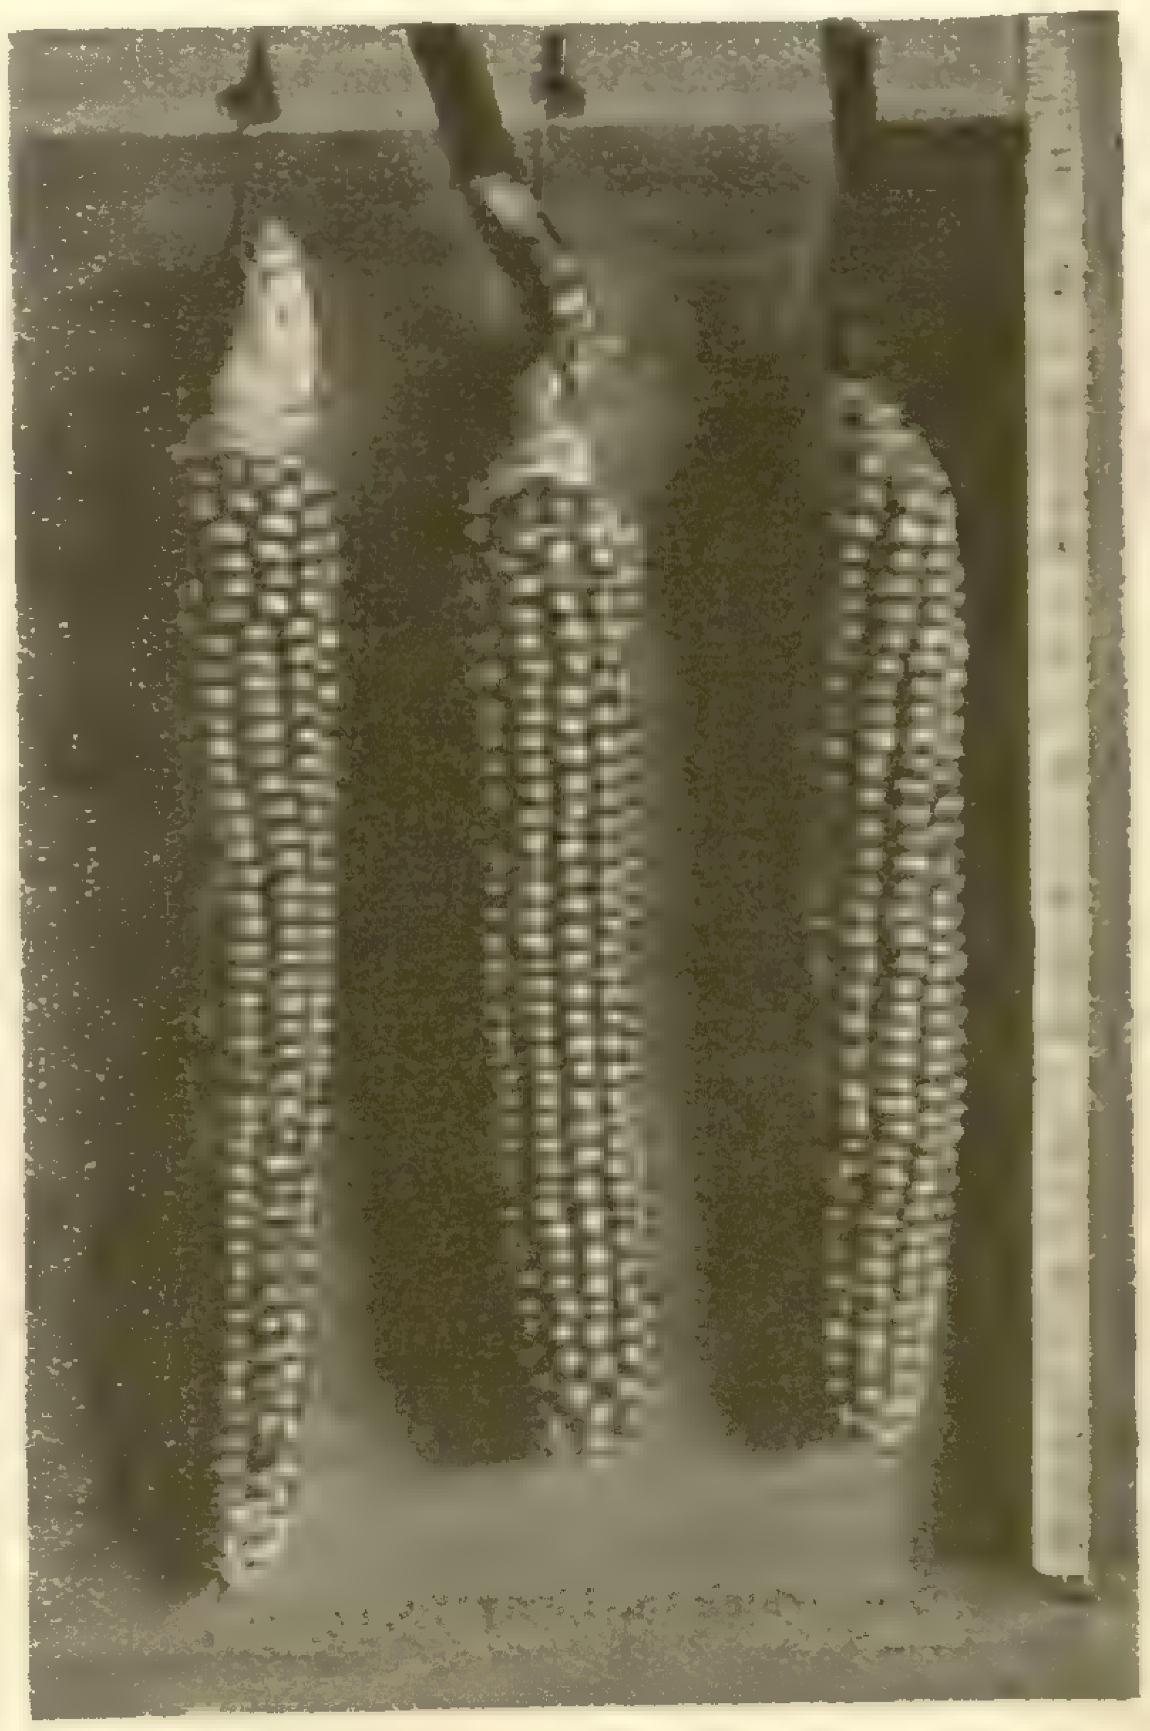

FIG. 4.—THREE LARGE MAIZE COBS GROWN IN 1918; THE FOOT RULE INDICATES THEIR SIZE.

about 4 inches high. The wet weather experienced in August evidently told against the plant, for when the crop was gathered, many cobs were found either not to have set at all, or to have set only a few seeds. I am inclined to attribute this to the lack of good pollen owing to the continuous wet weather. The cobs were eventually picked at the end of September and beginning of October, after which they were stored under cover preparatory to shelling them out. Before this was done they were examined in order to separate the thoroughly ripened cobs from those in which the ripening was not quite so good. The object of this was, of course, to ensure that the earliest and best cobs only should be used for seed in the following year. From the picked cobs 49 lbs. 4 ozs. of grain were obtained, while the inferior ones yielded 34 lbs. 13 ozs.—in all 84 lbs. 1 oz. from 137 square yards of land. This works out to a yield of 2,180 lbs. per acre, i.e., 39 bushels.

And here I may say a few words about the land on which the plants were grown. It is of a stiff nature, tending to pack closely after rain. The depth of soil is about one foot, the subsoil being untractable blue gault. Before being taken over for garden purposes in 1913 it had been much neglected, and for a year or two before that date had been allowed to be derelict. Since it was taken over a good deal of manure has been put into it, but although this has effected a marked improvement, it is still heavy and difficult to work when at all wet. Whether such land is favourable or unfavourable to the growth of Maize I cannot say, as I have not yet had the opportunity of growing it upon really good soil. I can state, however, that the soil of my garden is certainly not unduly favourable to the growth of most of the crops that I have hitherto attempted to raise on it.

Of the original parents of the Maize one was yellow and the other white. No selection was made in respect of colour, and the majority of cobs comprised a mixture of various shades of yellow, and of white seeds. Yellow, however, greatly predominated. During the present year seed was, as hitherto, retained from the best cobs of the year before, but this year I also selected a certain amount of white seed, and sowed this separately from the rest, which were principally yellow. The drills were 2 feet apart as before, but as previous experience had shown that germination was good, the seed was put about 6 inches apart in the drills. The patch on which the yellow was sown was 350 square yards, and that into which the white was put was 114 square yards. In either case the amount of seed used was at the rate of ½ bushel per acre. The season was unfavourable; in fact, my friend Dr. Guillemard, of Trumpington, told me that although he had grown Maize here for 27 years he had never known a worse one. Yet in spite of this the Maize cannot be said to have done badly. The yellow patch yielded 190 lbs. 10 ozs. of grain—equivalent to about 47 bushels per acre. The white did even better. From the smaller area sown with it 81 lbs. 2 ozs. were obtained, which is equal to a yield of over 61 bushels per acre. The patch of land used for the white was rather better than that on which the yellow was sown, but whether the increased yield of the white-seeded form was due to this, or to some other cause, it is impossible to say without further experiment. But as the largest cobs obtained (see fig. 4) were produced on the white patch, I am inclined to think the white form would prove a heavier yielder even under the same conditions.

In reckoning the yield the produce of all cobs giving grain was weighed. In some of these the grain, though quite fit for feeding to stock, was probably not sufficiently ripened to have germinated well. The seed became somewhat shrunken in the process of drying off, and lacked the glossy, semi-transparent appearance of well-matured grain. Such "tailings" amounted to somewhere between 10-20 per cent. of the total.

The results of 1918 constitute a distinct advance over those of 1917, and I feel little doubt that, if the process of selection be continued, a still higher yield can be realised in the future.

It occurred to me last year that it would be interesting to compare the yield of this early flint Maize with that of the early sweet corns grown in America. Accordingly I obtained from Messrs. Burpee, of Philadelphia, seed of four of the earliest and highest yielding of the sugar Maizes, viz., Catawba, Golden Bantam, Extra Early Cory, and Howling Mob. For the test a small piece of light, gravelly soil on the Cambridge University Farm was selected. It had been given no manure for two years, and then only a light dressing. A light crop therefore was to be expected, but as the experiment was designed to test the comparative yield of the varieties used this did not matter. The important point was that the patch was homogeneous, giving all of the varieties an equal chance. On May 14 the seeds of the four American varieties and of the yellow form of the early flint Maize were sown 6 inches apart in drills drawn at intervals of 2 feet. Germination was good except in the case of Golden Bantam, where

about 30 per cent. failed. In the poor soil used the plants of the Yellow Flint did not reach a height of more than about 4 feet, at least a foot less than they attained in the garden in the experiments already recorded. Golden Bantam reached about the same size; Catawba proved to be a little taller; while Howling Mob and Extra Early Cory made distinctly larger and more luxuriant growth. Of the sugar Maizes the purple Catawba ripened earliest, though somewhat later than the Yellow Flint. Of the rest, Howling Mob, with its larger cobs, was much the latest to ripen. None of the sugar Maizes, however, was so ripe as the flint when gathered at the beginning of October. After being dried and shelled out the seeds were weighed in each case, and from these results the yield in bushels per acre was calculated. They were as follows:—

	Bushels per acre.
Golden Bantam	12.7
Howling Mob	13.4
Catawba	20.9
Extra Early Cory.	25.2
Yellow Flint	41.8

The yield from the Yellow Flint was very much heavier than that from any of the sugar Maizes, while at the same time the seed, taken as a whole, was much better ripened. Though grown on light soil without manure, the yield of nearly 42 bushels is only 5 bushels short of the 47 bushels given by the same sample of seed grown in my garden. It would have been interesting to have had the yield of the white variety for comparison, but unfortunately I did not think of this at the time of sowing. It is evident, however, that from the standpoint of grain yield the flint is far in advance of the best of the early American sugar Maizes.

From the foregoing facts it is clear that in the south-eastern part of this country, at any rate, it is possible to grow flint Maize which ripens well and gives a good yield. Nor is the grain inferior in quality to that grown in such huge quantities in warmer climates. An analysis very kindly undertaken for me by Mr. F. W. Foreman, of the Cambridge University School of Agriculture, showed the protein content to be about 10.5 per cent., and that of oil 5.2 per cent. The oil content, upon which the high feeding value of Maize so largely depends, is about the same as that of the American flint Maizes taken as a whole, and is, of course, several times as great as that of the three staple cereals grown in this country.

A Maize yielding 50 bushels per acre, and I do not see why this should not be materially exceeded under favourable conditions, ought to be of considerable value to the small holder. It offers many advantages. Since it does not require sowing until the second week in May it can follow immediately upon a crop of winter vegetables. Once in the ground it requires very little attention. I have found that a single hoeing when the plants are about 4 inches high is all the notice that need be taken of the crop until the ripe cobs are picked. The plants make such rapid growth that all weeds are kept well in check, and when the stalks are eventually removed the land is found to be remarkably clean. Again, garnering the grain is a simple process. The stems of the ripe cob are brittle and easily snapped off as one walks down the rows collecting them. The husks are then stripped off and the cobs placed in an airy place under cover to dry off for shelling. For this operation, when dealing with small quantities, I have found an oyster knife to be a handy and efficient implement. As soon as the first row is loosened the rest will generally come off easily with the pressure of the thumb. I have kept no data as to the time taken by the operation, but from personal experience I should say that an average person should have no difficulty in shelling out about 5 lbs. per hour. In the case of the smallholder growing a few cwt., this part of the work can be done at any odd time, e.g., on wet days or during the long winter evenings. If larger quantities were grown it would be advisable to have some form of machine for the purpose. I gather from Burtt-Davy's book on *Maize* that there are many forms of machine in use, from small hand ones costing about a couple of pounds, up to large power-driven ones for dealing with big crops. A further advantage of Maize is that it is not attacked by birds—at any rate at present. So far as I know, its only enemies are rats, and perhaps rabbits and hares. Rats are apt to be troublesome where they are abundant, for they nibble the grain off the nearly ripe cobs where these are close to the ground. It is as well in such cases to walk down the rows about once a week from the early part of September onwards, and to pick off cobs which show signs of being nibbled. As they do not appear to be attacked until nearly ripe, such cobs will dry satisfactorily.

Taking all things into consideration it may be fairly claimed that there is no cereal crop so suited to the small-holder who wishes to grow a few sacks of grain for feeding to poultry or pigs. A plot of ¼ acre requires but 7 lbs. of seed, and should yield 12 bushels of grain, or even more. The cultivation is simple, and every operation from start to finish can be performed without the aid of either skilled labour or of machinery. Moreover, the feeding value of the grain, owing to the oil content, is higher than that of other cereals.

Whether Maize could be grown profitably as a farm crop is another consideration. A yield of 40-50 bushels compares favourably with any of the other cereals, especially in view of the fact that it is all pure food, without the indigestible husk that goes to swell the yield of Oats or Barley. One must remember, too, that Maize requires less than half the amount of seed as compared with the other cereals, so that the net yield is really a bushel or so greater than the apparent one. But although a heavier crop of grain may be produced, there remains the problem of the straw. Maize straw is certainly unsuitable for many of the purposes to which the straw of other cereals is put. But the problem might be solved if it could be used for paper-making. For this purpose Maize straw offers possibilities. It is less siliceous than that of other cereals, it bleaches well, and it has not the hard nodes which render the latter objectionable. Maize straw appears to have been used with some success for the manufacture of paper, both in Southern Europe and in the United States. I write without experience, but in view of the timber shortage which is likely to be with us for many years to come, the use of Maize straw as a source of raw material for paper might well be worth serious consideration. If it were found suitable I see no reason why Maize should not become a profitable crop for British agriculture. *R. C. Punnett.*

THE ALPINE GARDEN.

PRIMULA ACAULIS VAR. RUBRA.

THIS plant has proved a stumbling-block in the way of nomenclature. The name Primula acaulis var. rubra is that of Sibthorp and Smith, but it has been sent out from different sources as P. Sibthorpii, Hoffmannsegg; as P. amoena; and also as P. altaica. To enter upon a full discussion of the nomenclature is needless, but we have it on the highest authority that P. acaulis var. rubra is the correct title, and that it differs from Bieberstein's P. amoena by being scapeless. It is a red, or, rather, purple-flowered Primrose of much beauty, and deriving a high additional value from its precocity of flowering. It even surpasses in this respect our common Primrose, and well repays being planted in a sheltered spot, where it may continue to give a few flowers throughout late autumn and winter, breaking forth into a good display in early spring. The plant appears to like a moist bank, and in my garden is highly prized in such a position as well as on the level.

Although said to be the parent of the various red, purple, pink, and blue Primroses, I am not prepared to assent to this statement, as I have come across wilding Primroses of allied tints, but paler, in haunts of our wilding where there could be no influence of P. acaulis rubra. However this may be, P. acaulis rubra is a beautiful flower deserving the little care it demands.

PRIMULA PALINURI.

ONE of the European Primulas rarely met with in cultivation is the Italian species named P. Palinuri. It comes from Southern Italy in the Apennine regions. It is a remarkable species, allied to P. Auricula, but of very different appearance. It has an underground woody stem spreading over a good length, and very large, broad, light green, fleshy, oblong or ovate leaves serrated at the margin and without farina. The tall scape rises well above the large leaves and bears a one-sided umbel of drooping golden-yellow flowers on powdered pedicels and with leafy outer bracts which are also covered with white meal.

This distinct Primula is shy of flowering, and generally delays coming into bloom until the plants have attained a considerable size. It is not considered generally hardy, but may survive in a sheltered situation in the milder localities. It is therefore desirable to cultivate it in a cold frame or alpine house, where it will give satisfaction. P. Palinuri is increased by seeds or division. *S. Arnott.*

NOTES FROM LAMELLEN.

MY garden is, as my friend Mr. Farrer has described it in his book, *In a Yorkshire Garden*, "a glen in the hills" facing north-west, and is about six miles from the north coast of Cornwall. It is sheltered by high ground from the north, east, and south, but open to the prevailing north-west wind, though a high hill on the other side of the valley cuts off some of its force in the lower part.

The soil is a heavy loam overlying shale, except in the centre, where blue clay is beneath, and we suffer much from damp, through which we lose several Rhododendrons every year.

The garden is a chaos suffering from a plethora of seedlings and a perennial lack of labour, which results, when the owner is ill or away from home for any length of time, in heavy casualties among these seedlings.

Hybridisation is being worked at a good deal, chiefly among Rhododendrons and Daffodils, but in the latter case I am only a beginner, and have so far only produced two really good flowers from Bianca × triandrus. I have also made one or two attempts on Roses, Irises, Lilies, and Primulas, without much result, and so far have resisted the insidious invitation in Mr. Bowles' book to add Crocuses to the list.

In mid-February of 1918, Rhododendron 1,521, Wilson, flowered for the first time; 9 flowers in a loose truss, violet-rose (*Répertoire de Couleurs*), with a few darker spots. Corolla 6-7-lobed, 2¼ × 2½ inches. Filaments white, stamens black, stigma same colour as corolla. This is supposed to be R. strigillosum, but if so is not nearly so good a form as a scarlet flower sent me last spring by a friend in Sussex.

Rhododendron 1,435, W., gave 12 flowers in a loose truss, crimson-red without spots. Corolla 5-lobed, 1½ × 2 inches, filaments and stigma paler than corolla, stamens black. I have had no name for this plant.

R. maculiferum, 8-10 flowers in a loose truss, mauve-rose with a blotch of crimson at the base, and spots of the same colour on the three upper segments. Corolla 5-lobed, 1⅔ × 1¾ inch, stigma and filaments white, stamens brown.

R. Ririei, 7-9 flowers in a loose truss, pale heliotrope. Corolla 5-lobed, $2\frac{3}{4} \times 3$ inches. Filaments and stigma dark at base, paler at apex, stamens rich brown. A large flower of a beautiful and uncommon colour.

R. haematocheilum var., 6-7 flowers in a loose truss, pale violet-rose, paler within, unspotted. Corolla 7-lobed, 2 by $2\frac{1}{2}$ inches. Filaments white, stamens dark brown, stigma greenish-white.

R. haematocheilum var., 6-9 flowers in a loose truss, violet-rose, not quite so pale as above, unspotted, but with a small blotch of crimson at the base. Corolla 7-lobed, $1\frac{3}{4} \times 2$ inches.

End of February: R. polylepis × lutescens sent me by M. Mottet from M. de Vilmorin's garden at Verrières. A very pleasing little flower of pale flesh-colour merging into creamy-yellow, short in the tube and wide open. The flowers are in twos in the axils of the leaves, and are $1\frac{1}{2} \times 2\frac{1}{4}$ inches, 5-lobed, filaments and stigma creamy-white, stamens pale brown, the upper segments of the corolla being spotted with bistre-green. The leaves are midway between those of the two parents. I was puzzled to account for the pleasing colour being derived from the usual poor purple of R. polylepis (Harrovianum), until one of my seedlings from Wilson's seed (4,278 W.) produced flowers of a lovely shade of pink without a trace of purple in it.

First week in March: In the greenhouse another plant of M. de Vilmorin's, R. 7,710, flowered; 4 in a truss, white, with a large blotch of yellow shading into rich brown on the upper segment. Corolla 5-lobed, $3 \times 3\frac{3}{4}$ inches. Sweet-scented. Filaments and stigma white, stamens pale brown. Very like R. Veitchianum in appearance, but differing in the colour of the blotch, which is much darker, in not being so deeply cleft into segments, and in having oblong lanceolate leaves about $4\frac{1}{2}$ inches long. Also, it is very much hardier, two plants having stood the hard winter of 1916-17 unprotected out-of-doors without any injury, when several other species, such as R. Edgeworthii, were killed.

Middle of March: R. 10,071, Forrest, cuneatum, 5 in a truss, pale violet-rose with a few yellowish spots. Corolla 5-lobed, $1 \times 1\frac{3}{4}$ inch, almost salver-shaped, divisions deeply cleft. Filaments same colour as corolla, stamens pale brown, stigma yellowish-white.

R. 10,423 F., ravum, 4 flowers in a truss, violet-rose, rather darker than above, with a few crimson spots. Corolla 5-lobed, $1 \times 2\frac{1}{4}$ inches, almost salver-shaped, divisions deeply cleft. Filaments same colour as corolla, stamens pink and brown, stigma yellowish-white.

End of March: R. 5,848 F., hylothreptum, 10 flowers in a truss, second shade of rose-Neyron, with a deep blotch of black crimson at the base. Corolla 7-lobed, $1\frac{1}{2} \times 1\frac{1}{2}$ inch. Filaments rather paler than corolla, stamens brown, stigma yellowish-white. I had only one flower on a sickly plant.

Second week in April: A most remarkable flower appeared on a plant raised under the number 9,048 F. (habrotrichum), and almost exactly resembling that species in leaf, though the flower buds were quite different. 12-14 flowers in a truss, purple-rose, with a dark blotch at the base, and two broad lines of red spots at the junction of the topmost 3 segments. Corolla 5-lobed, campanulate, $1\frac{1}{2} \times 2$ inches. Filaments and stigma very pale pink, stamens brown.

The feature of the flower, however, was the extraordinary size of the calyx, which was quite half-way up the corolla on the upper side, of the same colour, and profusely spotted with red, almost giving the appearance of a hose-in-hose flower. Professor Balfour has named this species R. diphrocalyx.

Third week in April: A Rhododendron flowered, which had appeared as a rogue among seedlings of R. adenogynum (5,868 F. and 5,871 F.). 10-12 flowers in a truss, pale lilac-rose, darker outside, with a dense marking of crimson spots on the three upper segments. Corolla 7-lobed, $2\frac{3}{4} \times 4$ inches, openly campanulate. Filaments white, stamens light brown, stigma greenish-white. Leaves $1\frac{3}{4} \times 4\frac{1}{2}$ inches.

This plant seems likely to prove one of the best Chinese species, for it is a rapid-spreading grower of good garden habit, very hardy, and with an exceptionally fine flower.

Two of my friends, to whom I sent a truss, expressed the opinion that, since there was nothing like it among Forrest's dried flowers, it must be a Fortunei hybrid raised here or elsewhere. But I know that in the first place it appeared among the adenogynum seedlings, and has been grown here ever since, and, in the second, that I have never raised any Fortunei crosses. Also it is utterly unlike that series both in leaf and flower-bud.

R. prostigiatum (prostratum × fastigiatum). Several plants of this cross flowered in April and again in August. So far, the best of them

Fig. 5.—Tecophilaea cyanocrocus.

(See p. 16.)

was almost 2 inches across, 2 in a truss, bright violet-purple, stamens and stigma the same, unspotted, salver-shaped, and very floriferous.

R. 1,526, W., argyrophyllum, 12-16 flowers in a truss, violet-rose, unspotted. Corolla campanulate, 5-lobed, $1\frac{1}{2} \times 1\frac{1}{2}$ inch. Filaments paler than corolla, stamens dark brown, stigma yellowish-white.

Fourth week in April: R. Faberii, 6-8 flowers in a truss, white, with two patches of crimson spots from the base to about half-way up the two upper segments, and a tinge of light crimson inside and out of the centre of each segment from the middle to the extremity, giving an unusual appearance. Corolla 5-lobed.

R. 8,923, F., zaleucum. So far as I could judge from this, a first bloom, the flowers are in twos in the axils of the leaves at the end of the shoots. Individually, they are white-flushed violet-rose, with two broad groups of dark violet-rose spots on the upper segment. Corolla 5-lobed, $2 \times 2\frac{1}{2}$ inches, openly campanulate. Filaments white, stamens bright chestnut-brown, stigma greenish-white. In another plant which opened later the flowers were violet-rose.

First week in May: R. 1,885, W., = hypoglaucum, 9 flowers in a truss, 5-lobed, campanulate, 1 2-5 × 1 3-10 inch, white, with a thick spotting of crimson on the upper segments. Filaments white, stamens pink, stigma greenish-white.

Third week in May: A plant labelled 1,539 W. Taliense, flowered, but I am not sure that the name is right. Eight flowers in a truss, 6-7-lobed, broadly campanulate, 1 9-10 × $2\frac{1}{2}$ inches, blush-white, with a shading of rose outside the middle of the lobes, and a thick spotting of crimson at the base. Filaments white, stamens dark brown, stigma greenish-white.

R. 6,761 F., dichroanthum, 6 flowers in a loose truss. Corolla 5-lobed, rather narrowly bell-shaped, opening at the mouth, 1 7-10 × 1 4-5 inch, orange-red. Filaments pale orange, stamens dark brown, stigma yellowish-green.

A compact dwarf-growing plant with a whitish tomentum between the leaves and on the young shoots, and flowers of a remarkable colour.

Seedlings from R. Mrs. Butler. Apparently this is a natural hybrid × ponticum, being much of the colour of the latter, but larger, and with 6 lobes to the corolla. One of these plants was better than the others, and quite an acquisition.

Last week in May: R. 9,055 F., callimorphum, 6-7 flowers in a truss. Corolla 5-lobed, campanulate, and rather resembling R. Souliei, but smaller, and not opening so widely. Colour peach-blossom, 1 1-5 × 1 3-5 inch, with a blotch of crimson inside at the base. Filaments paler than corolla, stamens light brown, stigma tinged with pale yellowish-red. A very neat and pretty little plant.

First week in June: R. 6,762 F., pholidotum, 6 flowers in a truss, reddish-violet. Corolla 5-lobed, 1 1-10 × 1 7-10 inch. There is a dense spotting of brownish-crimson on the three upper lobes. Filaments and stigma white, stamens light brown. A distinct and pleasing colour.

June 6: Whilst weeding in one of the seedling beds, I became aware of a small Rhododendron in flower, which would otherwise have certainly escaped notice. It proved to be R. 7,857 W. = Tschonoskii. Four flowers in a truss. Corolla 5-lobed, 2-5 × 3-5 inch, pure white, campanulate, with a narrow tube, and very deeply cleft segments. The outside of the

tube was slightly flushed with rose. Filaments white, stamens light brown, stigma white with a slight tinge of green.

Second week in August: R. auriculatum flowered here for the first time. Nine flowers in a truss. Corolla 7-lobed, sweet-scented, white tinged with yellow at base, and with two lines of crimson blotches fading into pale yellow at the base of the upper segments, a rather narrow tube opening widely at the mouth, 3¼ × 4 inches. Stigma and filaments greenish-white, stamens very pale brown.

Miss Brennand's admirable picture in Mr. Millais' book gives a very good idea of the flower, but hardly shows how large it is. I put its pollen on to R. hippophaeoides, since, unfortunately, I had none of the larger Rhododendrons in flower, but the two are so far apart that the cross is hardly likely to have taken. Also, I fertilised it with the pollen of R. Cunningham's Yellow, kindly sent by a friend, but no seed resulted.

October: An imperfect flower of what is probably haematodes came out. It is a beautiful ruby-crimson on a dwarf, spreading plant.

The third week in December, Nobleanum, parvifolium, mucronulatum, and atrovirens were in full flower; micranthum was also just going over. Smith's Early Scarlet and barbatum had 6 or 8 flowers out. I have never known barbatum so early; there were also isolated flowers on Keiskei, lutescens, neriiflorum, haematocheilum, and ambkeys (ambiguum × Keysii), a queer little hybrid, raised here, which strongly resembles the pollen parent Keysii. Even a bud on R. zeylanicum was showing colour.

The most difficult problems to deal with in the way of seedlings in 1918 have been R. auriculatum and R. 6,777 F., sulfureum microform, formerly called brachyanthum, the former being woefully prone to damping off, and the latter strongly resenting the process of pricking out.

The beautiful blue Tecophilaea cyanocrocus (see fig. 5) was flowering in the greenhouse in December. I once saw it growing out-of-doors in the kitchen-garden at Enys, but should be grateful if anyone could tell me what conditions suit it best in the open.

Primulas do not do very well here—probably it is too damp—but Cockburniana grows and seeds itself profusely, and one year produced a natural hybrid or two with pulverulenta. Last year a lovely rose-coloured plant appeared, probably Bulleyana × pulverulenta, and this year I rather think P. saxatilis has crossed with obconica indoors.

Yearly some plants of P. nutans and P. spicata flower, but others die off, and I expect they need more attention than I can give them. Nor have I succeeded in saving seed from spicata. P. vincaeflora flowered in two years from seed, but slugs will go miles for it and eat out the whole crown, so it is difficult to keep alive.

Of other plants in the garden, Embothrium coccineum (the Chilean fire bush) is about 30 feet high, and happily does not seed here, but throws up a few suckers, one of which has now almost reached the top of the temperate-house at Kew. Magnolia Campbellii is also about 30 feet high, and growing rapidly, but has not yet produced a flower, whilst M. Delavayi flowered this year for the first time. The leaf is magnificent, but the flower is not so good as that of M. exoniensis, and appears to last only one day.

There are one or two very good trees of Cryptomeria japonica, and two fine Cupressus funebris over 40 feet high.

Podocarpus Totara stood the winter of 1916-17 and is growing well. The rare Athrotaxis selaginoides is now represented by three specimens, the tallest about 8 feet high. They were all raised from seed from the old plant, now unfortunately dead, which was 26 feet high, and a very pretty sight when at Christmas-time it was covered with its orange cones. *E. J. P. Magor, Lamellen, St. Tudy, Cornwall.*

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Asparagus.—This excellent vegetable may be forced early in frames on a hot-bed. If hot-beds have been made as I advised in my first calender the fermenting materials will have settled, and the frames may be placed in position, with a brick under each corner to allow them to stand evenly on the bed. Inside the frame place a layer an inch or so deep of old leaf-mould. Place the Asparagus roots on the leaf soil, just touching each other, and cover the crowns with about 4 inches of sifted soil. Give a good watering to complete the operation. Keep the lights closed, unless the temperature rises above 60°, when a little air should be admitted. Close the frame early, and use the syringe in favourable weather. Place fresh fermenting materials around the lights as the manure sinks; this advice applies to all hot-beds for the next three months.

Seakale.—This vegetable may be regarded as almost indispensable throughout the early months of the year. When frosts are holding other choice vegetables in check, the value of Seakale is enhanced. At this season the roots may be forced easily if they are placed in light soil in pots, boxes, or beds. If a forcing house is not available the roots will do equally well in a warm greenhouse, provided the crowns are covered and kept dark, using pots or boxes, or even a rough batten frame, with bags thrown over to exclude the light. Insert the required number of crowns at intervals of ten days, and syringe with tepid water when moisture is necessary.

Tomatos.—Tomato plants raised from seed sown in the autumn of 1918 have made steady growth, the mild weather having suited them. They will be greatly benefited by shifting them into 5 and 6-inch pots, according to their size and strength. Use a compost of loam, leaf-mould, and a dash of sand. Do not pot too firmly at this season; when potted grow the plants near the roof-glass in a house having a temperature of 50° to 55° by night. Be sparing with the water-can for some time to come.

Carrots.—Short-rooted forcing varieties of Carrots should be sown at intervals of a month for the next three months on prepared hot-beds or in heated pits. Sow the seed in 6 inches of prepared soil; that from under the potting bench is ideal for the purpose, adding some burnt garden refuse when mixing it. Sow the seed in drills made half an inch deep and let the rows be 9 inches apart. Water and syringe when needed. Inimitable, Parisian Forcing, and Champion Scarlet Horn are excellent first early varieties, with Early Gem and Favourite for later sowings.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Seasonable Remarks.—One of the chief difficulties the Orchid grower has to contend with in winter is the maintaining of proper atmospheric conditions in the houses owing to the changeableness of the climate. The quarter opened with a touch of wintry weather over the greater part of England, and following this cold, damp, foggy weather has been general, a state of conditions prevailing at the time of writing. The most severe weather is, more often than not, experienced during the early part of the year, and we may look forward to a soaking rain one day and the ground frozen quite hard the next; indeed, changes come so suddenly that there is no time to prepare for them. It is obvious, therefore, that a considerable amount of care and attention is necessary in order that the temperatures may not fluctuate greatly. In all Orchid houses there should be sufficient radiating surface to maintain the requisite temperature without having to overheat the pipes, and thus cause a dry atmosphere. If, in these days of fuel shortage, the heating apparatus is not able to afford sufficient warmth to meet the demands, much may be done to keep the houses at a comfortable temperature by the judicious use of protecting materials, such as mats or stout canvas nailed over all exposed ends and sides of the houses. These materials may be allowed to remain fixed in position until the end of February or middle of March. In severe weather similar materials may be employed to cover the lower portion of the roof-glass at night, but they should be removed in the morning when the temperature commences to rise. The stoke-hole, if of convenient size, will be found the most suitable place for storing these protective materials during the day, as there they may be spread out to thaw and dry ready for use again.

Temperatures.—There is little doubt but that the houses, speaking generally, are often kept too warm. At this season all Orchids require more or less fire-heat, but many would be far better in cooler atmospheric conditions than are often maintained. Taking Orchids as a whole, the plants are very sensitive to atmospheric influence, and no matter how careful the treatment is in other respects, they cannot long continue in a satisfactory condition unless suitable atmospheric conditions are maintained about them. I never advise the rigid observance of a stated temperature, but give the following figures as a guide for the present, the higher temperature to be reached about mid-day, and the lower ones in the early morning. East Indian or stove houses, day, 65° to 70°; night, 60° to 65°. Cattleya houses, day, 60° to 65°; night, 55° to 60°. Intermediate houses a few degrees lower, and cool or Odontoglossum houses, day, 55° to 60°; night, 50° to 55°. The outside conditions must be considered at all times, and in very severe weather the thermometer should show but little variation during the 24 hours.

PLANTS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

Cyclamen latifolium. — The florists' Cyclamen, now represented in six distinct types, is one of the most useful mid-winter flowers for either the plant houses or furnishing cut blooms. One-year-old plants now in flower require to be grown in a house having a mean temperature of 55°. Guard against excessive watering, and give the roots weak manure water occasionally. Cyclamens raised from seed sown last August or September should be pricked out in 2-inch pots; the soil should consist of a mixture of loam, peat, and rough sand. Grow the plants near the roof-glass in a temperature of 55° to 60°. Use an insecticide occasionally to keep the plants clear of insect pests.

Sweet Peas.—Sweet Peas raised from seed sown in 3- or 6-inch pots last October, and intended for early flowering under glass, should be potted in 9 or 10-inch pots filled with good loam, to which has been added a 7-inch potful of plant fertiliser to each barrowful of loam. Birch twigs will provide suitable supports in the early stages of growth. Stand the plants in a cool, airy place near the roof-glass.

Schizanthus.—Large flowering hybrids of Schizanthus are indispensable for the early decoration of greenhouses and conservatories. Plants raised from seed sown last August in small pots should now be ready for transferring to the pots in which they will flower. Place the plants near the roof-glass in a cool, airy greenhouse, and when rooted sufficiently in the fresh soil, water them occasionally with liquid manure.

Camellias.—These showy plants are in less favour now than formerly for supplying cut blooms and for decorative purposes generally. The plants will be very valuable in these times of fuel shortage, for they grow and flower well in a cool greenhouse. Large specimens planted out need only sufficient warmth to exclude frost. Care should be taken not to allow the roots to become dry; when watering, first sprinkle the border with a plant fertiliser. When weather

permits admit plenty of air to prolong the flowering period.

Preparations for Propagating.—The propagating houses should be got in readiness for seed sowing and rooting young stock. Let the interior of the house be thoroughly washed with water in which soft-soap and a little paraffin has been added. Provide fresh material for plunging pans or pots in, whether the bottom heat is furnished by hot-water pipes or fermenting material.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Second-Early Vinery.—By this time the Vines in second-early vineries should have been pruned and cleansed, the borders top-dressed with fresh compost, and every portion of the house made as clean as possible. When these operations have been completed the house may be closed for the purpose of obtaining successional bunches. Vines with their roots in inside borders are most suitable for starting at this date. If the borders are outside sufficient fermenting material to impart gentle warmth to the roots should be placed thereon and protected from heavy rains or snow. If the soil of the inside borders is at all dry it should be given sufficient tepid water to moisten it thoroughly. Maintain a fairly moist atmosphere and, on bright days, syringe the Vines when closing the house. Use sufficient fire-heat to maintain the night temperature at from 45° to 50°, allowing a slight rise by day. Young rods should be bent down in order to assist the buds to break evenly throughout the whole length of the shoot.

Strawberries.—A batch of Strawberry plants may be introduced into a forcing house which is about to be started. The plants should be top-dressed with a compost of loam, soot, and dry, pulverised horse-manure, or manure from a spent Mushroom-bed, first removing a layer of the surface soil. Make the new material firm in the pots. A position near the roof-glass at the apex of the house is suitable for Strawberry plants at this season. Growth should not be unduly hurried in the early stages of forcing, and close attention must be paid to watering, for the soil needs to be in a uniform condition of moisture.

Melons.—The present is a suitable time for sowing seeds of Melon. The plants will have the benefit of lengthening days, and, with the assistance of favourable weather, should yield ripe fruits by the end of April or early part of May. Sow the seeds in 2½-inch pots filled with fine loam mixed with a small quantity of leaf-mould. Plunge the seed-pots in a gentle hot-bed and cover them with a sheet of glass. Water is not required until the seeds germinate. As soon as the seedlings appear place the pots containing them on a shelf near the roof-glass where there is no danger from cold draughts. A mild hot-bed formed of leaves and stable litter (previously prepared) should be made in the house, and on it should be placed a firm ridge of stiff loam mixed with a fair quantity of wood-ash and old plaster-rubble. When the plants are sufficiently advanced in growth set them out 2 feet apart. Maintain a night temperature of 60° to 65°, with a suitable rise by day.

Late Vineries.—All bunches of Grapes hanging on the Vines should be cut and stored in a Grape-room where the atmosphere can be kept dry and a temperature of 45° to 50° be maintained. The bunches should be examined carefully and all injured or decaying berries cut out. Prune the Vines forthwith, shortening each lateral to two good basal buds—that is, if the spur method of pruning is adopted. This method is suitable for free-fruiting varieties, but for certain sorts, including Lady Hutt and Duke of Buccleuch, it is advisable to leave an extra bud or two to ensure a fruitful shoot; should a growth from the basal buds produce a suitable bunch the extra buds can be removed; usually, however, it will be found that the end bud will be stronger in growth and produce the finest bunch. The objection to long and unsightly spurs can be obviated by training up young rods as occasion requires. To afford the Vines the benefit of a perfect rest allow the ventilators to remain fully open (except when frosts are very severe or during stormy weather). If the water-pipes are emptied the Vines will not be injured by frost, which would kill many insect pests. If the Vines are infested with mealy bug or red spider, remove all loose bark, particularly from about the spurs, and then thoroughly wash them by means of a suitable brush with fairly strong insecticide. Cyaniding is the most effectual method of eradicating mealy bug, but the inexperienced operator had better obtain expert advice before carrying out this dangerous operation. The house should be thoroughly cleansed, including every portion of the wood, ironwork and glass. Thoroughly wash the walls with fresh lime mixed with flowers of sulphur. After removing the surface soil of the borders top-dress them with fresh compost made of good loam, freely mixed with wood-ash, fine mortar-rubble and concentrated Vine-manure.

Cucumbers.—Seed of some approved variety of Cucumber should be sown forthwith. Insert one seed in each pot, which should be of small size and filled with light soil mixed with leaf-mould. Plunge the pots in a mild hot-bed and cover them with a sheet of glass. Let the young plants receive plenty of sunlight as soon as they appear. Fermenting material should be prepared for planting-time, and the required amount of fibrous loam placed under cover in readiness for use.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Apples that Cropped Well in 1918.—It may interest readers to give the names of a few varieties of Apples which bore heavy crops here last season, when nearly all the rest were total failures. Of cooking varieties Bramley's Seedling and Lord Grosvenor gave heavy crops; Bismarck and Stirling Castle gave good yields; Bess Pool and Lane's Prince Albert fair returns. Among dessert varieties trees of Rival were very heavily fruited, whilst Blenheim Pippin, Boston Russet, and King of Tompkins' County all carried good crops. As the Apple crop was so light generally it behoves those who have fruits in the fruit-room to keep a constant watch over them with a view of removing at once all which are not keeping well; admit a little air to the fruit-room whenever conditions are favourable.

Peaches.—If the cleansing and tying of Peach trees out-of-doors has not been done, the work should be completed before the buds begin to swell, otherwise there will be a danger of breaking many of them from the branches. The trunks and main branches should be scrubbed with a stiff brush, and the young shoots with a soft paint-brush. Gishurst compound is the best specific to use, unless mealy bug is present, when XL All insecticide should be employed. If the trees are clean and labour short, it is not necessary to untie all the branches, provided they are syringed with alkali wash before the buds begin to swell. Examine all ties to see that the wood has room to swell, and remove as much of the old wood as can be spared. When this work is completed, take away the trellis or boards which have been used by the operator for standing on; remove all sour soil from the border, and substitute a mixture of old loam, lime rubble, bone meal, and wood ash, at the rate of 8 parts loam, 1 part lime rubble, 1 part wood ash and 4 stone of bone meal. Much depends on the nature of the loam: if it is very heavy in texture, use more lime rubble. The whole of the materials should be mixed thoroughly two or three times by turning with a spade. Any trees that are making gross shoots, and have not yet been root-pruned, may still receive this attention, but it is not advisable to root-prune more than one-half of the tree at one time. The work may be completed next autumn, which is the best time to root-prune.

Apricots.—All work, such as tying the shoots and top-dressing the roots, necessary for Apricots, should be completed forthwith. As a rule the trees do not need much cleansing in winter, but they occasionally get infested with scale, which may easily be removed by washing with Gishurst compound. Apricots are probably the most difficult of all fruit trees to manage, for sometimes half the number of shoots die, from no apparent cause. Much of the trouble may be traced to unsuitable rooting conditions, and I find that dying of the branches does not occur where there is good, deep drainage, and suitable compost, which should consist of loam, lime rubble, brick rubbish, and chalk, if procurable. A porous border is essential to success, and the trees will not tolerate a stagnant border. It is not advisable to give rich mulchings; a covering of dry litter is useful in winter, as it protects the borders from frost and rain. The best time to apply the mulch is after the crop is set.

Top-dressing.—Rank manures should not be used for this purpose: a mixture of well-decayed leaf-mould and manure provides the best mulch, and in addition the borders should receive a good sprinkling of burnt refuse and mortar rubble.

Liming Fruit Trees.—Soils deficient in lime should receive a good dressing of quicklime. I prefer to use it after it has been slaked. Apples, Pears, and berry-bearing bush fruits are all benefited by a dressing, but lime is especially desirable for stone fruits.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Roses.—The present is a suitable time to secure Briars for budding during the coming season. Select those with young, healthy, clean stems ranging from 3 to 6 feet in height, trim the roots and plant when the weather is suitable, allowing sufficient space between the rows to do the work of budding with comfort.

Protecting Plants.—Owing to the mild weather, many bulbs are making precocious growth, and should a change to severe weather occur serious damage may result unless protection is afforded the plants. I know of no better protective materials for bulbs and similar plants than leaf-mould or Coconut fibre refuse; and these should be scattered over the shoots peeping through the ground before the plants get injured and before the frost penetrates deep in the soil. Keep a watchful eye on all choice bulbs planted in nooks and recesses, protecting these very carefully should there be signs of very severe weather. Have an abundance of suitable material in readiness for protecting choice and tender shrubs, there being several kinds that will withstand a reasonable amount of frost but would succumb to a rather sharp winter.

Wichuraiana Roses.—There are many very excellent varieties of this class of Rose which can be utilised in a variety of ways to give a good and pleasing effect. They are suited for covering old, unsightly buildings and fences. A few varieties planted in good soil with ample drainage will grow quickly, and in a very short time clothe what was formerly an eyesore with a mass of both foliage and flower. Alberic Barbier, Elisa Robichon, Excelsa, Francois Guillot, Hiawatha, Jersey Beauty, Joseph Billiard, Paul Transon, René André, and others, may be planted, and will withstand many degrees of frost without being injured. Fully established plants which have already covered much space should be thoroughly mulched or liberally fed with liquid manure at intervals during dry weather in the growing season.

Dwarf Roses.—In order to maintain in vigour and health Roses which have occupied the same position for several years, the roots should be fed and top-dressed with decayed farmyard manure. Where the soil is close and sour the plants may be lifted entirely, the roots pruned with a keen-edged pruning knife, and replanted in a fresh, sweet, suitable compost, resting on perfect drainage. The improvement in many cases will be most marked. In preparing beds for planting, pay great heed to the drainage, and take every care to have the soil prepared thoroughly.

Plants in Tubs.—Agapanthus, Myrtle, Agave, and other tender plants growing in large pots or tubs should be kept safe from frost. A temperature of 45°—a little more or less, according to the weather—is suitable to keep the plants healthy. Keep the roots just moist, but do not allow the soil to become excessively dry.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

SALES FOR THE ENSUING WEEK.

WEDNESDAY, JANUARY 15—
Sale of Roses, Fruit Trees, &c., at 67, Cheapside, by Messrs. Protheroe & Morris, at 1 o'clock.

THURSDAY and FRIDAY, JANUARY 16 and 17—
Sale of 17,000 Fruit Trees, Ornamental Trees, &c., at Cheshunt Nurseries, Cheshunt, by order of Messrs. Paul & Son (Cheshunt), Limited, at 11.30 o'clock.

SATURDAY, JANUARY 18—
Sale of Hollies, Rhododendrons, &c., at the High Beech Nurseries, Loughton, by order of Messrs. Paul & Son (Cheshunt), Limited, at 11.30 o'clock.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 37.9°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, January 8, 10 a.m.: Bar. 38.2; temp. 47°. Weather—Dull.

Senecio saxifragoides and S. lagopus. An interesting phenomenon in plant distribution is exhibited by these two species of New Zealand Senecios. The one, S. lagopus, occurs in the main mass of the Banks Peninsula, on the E. coast of South Island; the other, absent from the peninsula, occurs in the Port Hills.

This problem has recently been investigated by Prof. A. Wall,* who shows that the two species are identical in all respects save one. Even this one differentiating character is quantitative, and not qualitative, and concerns the location of the so-called "bristles"—actually glandular hairs which occur on the leaves. Though present in both species, the distribution of the hairs is consistently different in the two species, and a similar difference of distribution in the other, silky hairs, characterises S. saxifragoides and S. lagopus.

Yet—and herein is the point of interest—the two forms have distinct stations.

That they are members of one species cannot be doubted, in view of their general identity of characters, but why they should exhibit this remarkable spatial segregation is a puzzle. The only plausible explanation is that they represent geographical, or rather, climatic, varieties, each representing the state of hairiness concordant with the special climatic conditions of their several habitats. In support of this view, Prof. Wall draws attention to the fact that the Port Hills, on which S. saxifragoides flourishes, are nowhere higher than 1,800 feet, whereas other peaks on the peninsula reach to 800 feet above this level. The rainfall in the former station is about 25 inches per annum: that of Akaroa, on the peninsula, and a station of S. lagopus, is 44 inches. Hence it may be that it is to the drier climate of the Port Hills and to the wetter climate of the higher parts of the peninsula that the differences in hairiness exhibited by the two species are to be referred.

It is to be hoped that Prof. Wall will investigate this problem experimentally, and it would be particularly interesting to know whether seed or plants of the one species transplanted and raised in the habitat of the other would or would not remain constant to their several types.

Examples of a similar nature among animals have been investigated by Loeb and other zoologists. For instance, "The two species of salamander, Salamandra atra and S. maculosa, occupy distinct stations. The former occurs in dry alpine regions of relatively low temperature; the latter, in lower regions, with plenty of water and higher temperature. In the dry alpine regions S. atra deposits eggs, which hatch out as land animals; in the wet lowlands the eggs laid by S. maculosa contain embryos in a less advanced stage of development. The young when born are gill-bearing, and complete their development whilst leading an aquatic mode of life. Thus each species is adapted to the physical conditions of its environment.

"But if S. atra is exposed to lowland conditions, that is, to a moist atmosphere and relatively high temperature, it lays its eggs earlier, the young hatch out in the gill-bearing stage, and development is completed during their life as independent aquatic animals. Conversely, if S. maculosa is exposed to alpine conditions, oviposition does not take place till the embryos have passed beyond the aquatic gill-bearing phase.† " It would seem, therefore, as though a pretty piece of experimental work is waiting to be done on the two species of Senecio which form the subject of Prof. Wall's paper.

* "On the Distribution of Senecio saxifragoides Hook. f. and its Relation to S. lagopus, Raoul," *Trans. N.Z. Institute*, L., 1917. (Issued June 10, 1918.)

† *Plant Animals.* The Cambridge Manuals of Science. By Frederick Keeble. (Cambridge Univ. Press.

Gardeners' Royal Benevolent Institution.—The seventy-ninth annual general meeting of the members and subscribers of this Institution will be held at Simpson's Restaurant, 101, Strand, London, on Thursday, January 23, at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the Institution (as audited) for the year 1918; electing officers for the year 1919; and for the election of fifteen annuitants on the funds. The chair will be taken by Sir HARRY J. VEITCH, F.L.S., V.M.H., treasurer and chairman of committee, at 2.45 p.m. The poll will be open at 3 p.m. and close at 4 p.m.

Honour for Major F. B. Pulham.—The Order of the British Empire has been conferred on Major F. B. PULHAM, of Messrs. PULHAM AND SON, Newman Street, Oxford Street, London, and Broxbourne, for "meritorious service during the war." Major PULHAM obtained his commission in 1914.

Orchids in France.—Writing from Brunoy, Seine et Oise, France, last week, Monsieur CHAS. MARON states: "After an anxious time, during which I had to shut off the heat from half my Orchid houses and make shift as best I could to accommodate my collection by turning out of pots some of the largest specimens, I am now glad to be able to inform you that we are coming out of this dreadful war in much better condition than I had expected. There have been regrettable losses, of course, but we are thankful for having been able to save the greater part of the good hybrids, and later I hope to tell you of some very interesting plants. My son has passed through his Army duties in good health."

Agricultural Wages.—Employers or workers who do not understand their position under the Orders issued from time to time by the Wages Board can usually obtain the information they need by writing to the Secretary of the Board, 80, Pall Mall, S.W. 1. Attention to the following points will facilitate correspondence: (1) Mention the county to which your question refers, (2) give a full address on your letter, (3) state your question as clearly and as shortly as possible, and (4) letters to the Wages Board may be sent unstamped.

The Surveyors' Institution.—The next ordinary general meeting of the Surveyors' Institution will be held in the Lecture Hall of the Institution on Monday, the 13th inst., when a paper on "The Second Report of the Committee dealing with the Law and Practice relating to the Acquisition and Valuation of Land for Public Purposes" will be read by Mr. EUSTACE HILLS. The chair will be taken at 5 o'clock.

County Marketing Schemes.—The Framlingham Egg Collecting Society—one of the most successful of its kind in the world—is in negotiation with the Horticultural Sub-Committee of West Suffolk with a view to undertaking a marketing scheme in co-operation with the Sub-Committee. In East Suffolk the Horticultural Sub-Committee is negotiating with the Ipswich Industrial Co-Operative Society in reference to improved market facilities. A Cumberland Fruit and Vegetable Society has been successfully launched, and is stated to have an exceptionally well arranged central dépôt.

New Steamers for Overseas Fruit Trade.—Messrs. ELDERS AND FYFFES, who occupy a prominent position as importers of Bananas and other exotic fruits, have placed an order for three new steamers with Messrs. CAMMELL LAIRD, of Birkenhead. The vessels are to have a speed of 15 knots, and they will be built so as to secure the maximum amount of space for fruit carriage.

Double Wedding at Newry. — On St. Stephen's Day, 1918, two interesting weddings were solemnised in St. Mary's Church, Newry. At 10.30 a.m. Miss E. S. SMITH was married to Mr. THOS. GRILLS, of Fermoy; and at 11 o'clock Second Lieut. NORMAN SMITH, Royal Flying Corps (a recently returned prisoner from Germany), married Miss G. C. LOCKE. Second Lieut. N. SMITH and Miss E. S. SMITH are the son and daughter of Mr. GEO. NORMAN SMITH, and grandson and granddaughter of Mr. THOS. SMITH, Daisy Hill Nurseries, Newry. St. Mary's Church was decorated for the weddings and the Christmas festivities by Miss HETTY SMITH, with material largely obtained from the Daisy Hill Nurseries.

Wolverhampton Floral Fête.—Mr. GEORGE W. A. MARTIN, secretary of the Wolverhampton Floral Fête, informs us that his committee has decided to resume the Floral Fête this year, and that it is to be held on two days, Wednesday and Thursday, July 9 and 10, 1919, instead of three days, as in former years.

Nitrate of Soda.—The Government is offering a certain amount of nitrate of soda for delivery in the early months of 1919, at the price of £20 per ton, in bags. This price is for quantities of not less than 2 tons, delivered to purchaser's nearest railway station in Great Britain. The minimum order accepted for delivery direct from Government store to purchaser's or consumer's station, according to the Food Production Department, will be not less than 2 tons, but smaller quantities may be bought from the stores of agricultural merchants or co-operative societies. In these cases, special additions to the above-mentioned prices have been authorised.

Gardener's Death from Tetanus.—A verdict of "Death from tetanus" was returned at an inquest recently held at the Royal Devon and

19, Bedford Chambers, Covent Garden,

London, W.C.

NOW IS THE TIME TO PLANT PAEONIES

The war is over and we have kept our stock intact, although many other plants have ceased to exist in our Nurseries owing to the withdrawal of labour. There is no plant so satisfactory as the PÆONY to plant for permanence in a garden. It is essentially perennial, and hard to kill by neglect.

The plants we are now offering, owing to the war, are larger than usual and full of bud, and planted now should be in a good flowering state next year and for many years to come.

We offer Collections, chiefly English varieties raised in our Nurseries, and comprising all the various colours strong as well as delicate, for which the Pæony is celebrated.

"EVERYTHING FOR THE GARDEN."

Wm. BIGNELL & SON,

North Road, Highgate, N. 6.

Exeter Hospital on the body of Mr. Joel H. Crosscombe gardener at Belmont Pleasure Ground. The deceased man cut one of his fingers, and four days later complained of stiffness of the neck; two days afterwards he went to the hospital, and had his finger dressed. The following morning, being unable to swallow or move his jaw, he was taken to the hospital. The widow said at the inquest that before her husband cut his finger with a pruning hook he might have been engaged in potting, in which he would have soil mixed with manure to deal with. The house surgeon considered deceased came to the hospital too late for serum to be of any value.

Japanese Rice Crop.—The production of Rice (uncleaned) in Japan is estimated at 209,959,000 cwt., or 8.1 per cent. above last year and 4.4 per cent. above the average of the five years 1912-16.

Wart Disease of Potatos.—A survey of the whole of the counties of England and Wales was undertaken lately by the Food Production Department in order to ascertain in what areas wart disease exists. As a result 68 districts have had to be certified as infected areas under the Wart Disease of Potatos Order, 1918. Among the areas so certified are a district including the county of Glamorgan and parts of the county of Monmouth, Carmarthen, and Brecon; the whole of Lancashire south of the River Ribble, and a number of parishes in the counties of Nottingham and Derby. The county of Stafford is to be declared an infected area as and from January 1, 1920.

Land Drainage.—During the past two years the subject of improving the main drainage channels has been taken up with great enthusiasm in Yorkshire, among other counties, and remarkable results have been achieved at a comparatively small cost. The low-lying lands around Doncaster and on the North Bank of the Humber are provided with long-existing drainage systems, but many of these were in a state of great neglect when the Agricultural Executive of the East and West Ridings turned their attention to this matter in the spring of 1917. In the East Riding the cleansing of the Groenoak Goit was completed in 1917, and about 2,000 acres were greatly improved thereby at a cost of £600. Work on the Bellasize Drain was completed in October, 1918, in spite of difficulties caused by the shifting nature of the sandy clay soil. The drain is now said to be working more efficiently than it has done for 70 years past, and an area of approximately 4,000 acres has been greatly benefited at an expense of about £1,200. The water in the Market Weighton Canal (which forms the outlet of the River Foulness) has been substantially lowered by the regulation of the lock gates giving on to the Humber, and the cleansing of the canal is being carried out; the area which will ultimately be benefited by this work extends to about 20,000 acres. The Committee have commenced work upon the clearance of the Howden drainage system. The following is a brief summary of the principal work carried out by the West Riding Agricultural Executive Committee: West Moor and Parks Drains.—Area improved, 3,327 acres; area reclaimed, 700 acres; estimated cost, £1,365. Tickhill.—Area improved, 2,750 acres; area reclaimed, 200 acres; actual cost, £364 18s. 4d. Thorne.—Area improved, 13,000 acres; area reclaimed, 200 acres; estimated cost, £2,700. Gowdall.—Area improved, 700 acres; estimated cost, £250. River Don.—Area improved, by clearing a short and much-congested reach, 40,000 acres; estimated cost £500. Awkley Bridge (River Torne).—Area improved, 2,000 acres; actual cost, £17; arches altered by County Council and other work undertaken by private owners. Awkley and Blaxton.—Area affected, 2,500 acres; estimated cost, £50. Doncaster and Balby Car.—Area improved, 300 acres. Lower Anker Drain.—Area improved, 250 acres; estimated cost, £140. Tranmoor Drain.—Area improved, 150 acres; estimated cost, £50. Little Went Drainage.—On representation by the committee the Little Went has been cleaned out by co-operation of adjoining owners; this is not known to have been done before at any time, and the improvement is considerable. Similar work has been done (to give only a few instances) in counties so far apart as the North Riding of Yorkshire, Norfolk, Berkshire, Cheshire, Lancashire, and Flintshire.

ROSA MOYESII VAR. FARGESII.

A handsome Rose has appeared in cultivation under the name of Rosa Fargesii, the botanical source of which I have been unable to trace. In any case its characters agree so closely with those of the now well-known Rosa Moyesii, Hemsl. and Wils. (*Bot. Mag.*, t. 8,328) that it can only be considered as a variety of that striking Rose. There are bushes of both in the Kew collection, which I carefully compared when in bloom, and found an almost complete agreement in habit, armature, foliage, and in the large flowers with deep crimson petals—characters which are found in no other species of Rose. A fruiting branch of the so-called Rosa Fargesii, illustrated in fig. 6, shows the graceful character of the fruits and foliage. The fruits are about 2 inches long, bright red in colour, clothed with numerous slender, glandular bristles, and crowned with the persistent sepals, which are united at the base into a short cup. As to the origin of this Rose, we may assume that it is an introduction of the Rev. Paul Farges, a French missionary, who made extensive collections in North-east Szechuen, near the borders of Shan-si and the Ta-pa-shan Mountains, though it is not included in a list of his novelties described by Franchet. According to the latter author, Farges' collections in 1896 amounted to about two thousand in number, and he was still collecting in the same mountainous region, which, by the way, is within the area of Rosa Moyesii. His collections are at Paris, and duplicates of some of them are at Kew, though I find no specimen of this particular Rose in the Kew Herbarium. The Kew plant of R. Fargesii was received from Messrs. James Veitch and Sons in 1913, which is all that I have been able to ascertain of its history. It is a graceful and beautiful plant, whether in flower or fruit. *R. A. Rolfe.*

Fig. 6.—Fruits of Rosa Moyesii var. Fargesii.

THE MARKET FRUIT GARDEN.

December was an exasperating month, owing to the frequent interruptions to work in the open by rain. It was not that the rainfall was heavy, only 2.48 inches being recorded here, but there were only five days quite clear of rain. The ground was always wet, so that practically no progress could be made with digging or horse cultivation. The weather was remarkably mild, frost seldom holding long after sunrise, so that the ground was at no time frost-bound. For this reason weeds and grass have continued to grow, and land that was fairly clean when hoeing finished in autumn now looks quite green, and will have to be dug. Good progress has, however, been made with pruning, considering the shortage of skilled labour.

Rabbits and Fruit Trees.

I did not have to wait long to learn whether a low band of wire netting would suffice to prevent rabbits from gnawing fruit trees. Although there has been no severe weather, rabbits appear to be unusually troublesome this winter, and they have done considerable damage amongst newly-planted trees. So far from being afraid of the netting, the rabbits evidently find it a convenience, resting their fore-feet on it and gnawing any part of the tree within reach. They have done this even where the netting is 18 inches high, which has hitherto been considered a sufficient safeguard. Apparently nothing under 2 feet affords complete protection. This means that, if bush trees are to be planted, a rabbit-proof fence must be erected around the plantation—a very expensive business, and practically impossible in present conditions. One other plan has been recommended to me by a market-gardener of life-long experience, who affirms that it has proved successful in his case and that of others to whom he has given the hint. This consists of a low fence of tarred string, one strand about 6 inches from the ground and another 4 inches higher. He affirms that, so long as the tar is fresh, rabbits will not pass such an obstacle, and that tarring three or four times a year is all that is required. This simple plan seems too good to the true, but I am giving it a trial. Stakes 2 feet long have been driven in around the plantation, 12 feet apart, and the string dressed by drawing it through a watering-can full of tar, a stick being pushed into the spout to prevent the string from

carrying out too generous a coating. It was dirty work, but very soon done. Possibly some reader has tried the plan and can report on the result. Mr. Davis (p. 261, Vol. XLIV.) advises me to use Bentley's tree-protecting paint instead of wire netting. This, however, could hardly be applied to bushes, as branches as well as stems would, I assume, have to be painted.

AMERICAN BLIGHT.

This pest has spread so seriously during the past year that an unusual amount of interest is being shown in its eradication. Local applications brushed into affected spots on the branches are all very well on a small scale, but are almost out of the question where large plantations have to be treated, particularly where the young shoots are attacked. A correspondent, who realises this difficulty, asks whether there is any more effective way of dealing with this pest than by spraying in winter with a caustic solution and in summer with a suitable aphis wash. I do not think there is, and that is the plan I mean to adopt. It is known that a solution of $2\frac{1}{2}$ lbs. caustic soda (98 per cent. pure) in 10 gallons of water, used on the dormant trees, will kill any of the insects it touches. The Woburn winter wash, which contains a paraffin emulsion in addition to caustic soda, is said to be rather better for the purpose, but the makers could not supply me this winter. For summer use, any good aphis wash answers, provided that it touches the insects, but preference should be given to one containing nicotine or a paraffin emulsion. Another wash that has been used with marked success, as stated by Mr. R. P. Brotherston in a recent issue, is Gishurst compound at the rate of 2 oz. to the gallon of water. A more important point than the selection of the wash, however, is the thoroughness of its application. About this there is general agreement. The insects are killed only if they are thoroughly wetted, and they are well protected, both by their woolly covering and by the position they take up on the tree. For this reason a coarse nozzle must be used, the trees thoroughly drenched, and the spray directed with force into affected spots. One application of the winter wash should suffice, but the summer treatment must be repeated as required. Persistent treatment can hardly fail to hold the pest in check, though it is probably too much to expect that it can be completely eradicated.

So far I have dealt only with American blight above-ground. When it occurs also on the roots the matter is much more serious. The advice has been given to uncover the roots in winter and apply a caustic wash, and my correspondent asks whether this is practical. On a large scale it certainly is not. The only alternative is to use injections of carbon bisulphide. Four or more injections are made in the ground around each tree 2 feet from the stem, using 2 to 4 oz. of the liquid in a Vermorel injector. Theobald, who advises this treatment, says that it must be done before April and whilst the soil is fairly dry. I have no experience of this practice, but I believe that it would be much too expensive to apply on a large scale. So far, however, I have had no trouble with the blight below-ground. Several trees were recently lifted because the branches were hopelessly attacked, but no sign of the trouble could be found on the roots. There is no doubt, however, that the root form does occur in other places. Even then it would appear that persistent treatment above-ground must clear the roots in time, for Theobald says that no eggs have ever been found below-ground, and that the colonies of insects on the roots can only be replenished by migrants from the head of the tree.

WINTER SPRAYING.

Since we are approaching the season chosen by most growers for winter spraying, it will be well to consider what results we may reasonably expect from the operation. When the practice first came into common use, very extravagant claims were made for it. The trees were to be cleared entirely of insect eggs and fungus spores, and clean, healthy crops would be produced. It was soon found that these claims were not justified. Authorities now hold out little hope that we can do more than rid the trees of mossy growth, for which purpose spraying once every three years is sufficient in most districts. At the same time, of course, any exposed insects are killed; but insect eggs apparently resist the strongest washes we can use without injury to the trees, whilst it is doubtful whether anything can be done against fungi in their winter resting stages. On this latter point Massee states that "no known fungicide can cure a disease, neither can a fungicide kill fungous spores. All that it can do is, when properly deposited on a leaf or a fruit, to kill the germinating spores that alight on the surface." This means that fungicides are of no use in winter, but only as a preventive when the trees are in active growth. This seems reasonable, since the mycelium of such a disease as scab or brown rot is within the tissues of dead spurs, young shoots, etc., in winter, where it cannot be touched by spraying. If we accept this theory, there is no object in going to the expense of making our winter wash a fungicide. Winter spraying simply to cleanse the trees of moss and loose bark is, however, well worth while, as these encumbrances are against the well-being of the tree, and they serve to protect insect pests.

HOW OPINIONS DIFFER.

It is worthy of mention that growers are by no means all in agreement with mycologists and entomologists as to the limitations of winter spraying. They also differ very much amongst themselves. For instance, Mr. A. Mirkin, a well-known Kent grower, affirms that he very largely controls Apple scab and brown rot by spraying with lime-sulphur whilst the trees are dormant, also that it has some action on the eggs of aphis and psylla. Mr. W. P. Seabrook, on the contrary, writes that lime-sulphur "is of very little use as a fungicide in winter apparently," but he always uses it in January or soon after because he finds it to be "of great efficacy in enormously minimising aphis attack." Yet Theobald, after careful experiments, has declared lime-sulphur to be of little value for destroying aphis eggs. As a winter fungicide Mr. Seabrook is a great believer in sulphate of copper, 4 to 10 lbs. to 100 gallons of water, stating that it is usually efficacious in the cases of canker, brown rot, black scab, and coral spot. He has had little success with Bordeaux mixture applied in summer at the usual strength. Thus it is seen that scientists and growers differ widely. On paper the former can produce the more convincing evidence, but it is impossible not to attach some weight to the opinions of experienced growers, who are also keen business men and unlikely to continue practices unless they were convinced that they paid. There is, I consider, a wide field for further investigations in the use of insecticides and fungicides. *Market Grower.*

ON INCREASED FOOD PRODUCTION.

BEST USE FOR TURVES.

MANY allotment holders, when making their plots, skimmed off the turves and piled them to rot. In a large number of cases also allotment holders used their turves to make rough tool-sheds, seats, dividing walls or barriers, frames, and so on. It cannot be too strongly urged upon such allotment holders that the best purpose to which they can put decayed turves is to break them up and dig them into their plots. Farmyard manure and similar bulky manures are very scarce, and the best substitute where these cannot be obtained is rotted fibrous matter, such as turves. According to reports recently received there seem to be many thousands of tons of these stacked turves standing in one form or another on the allotment grounds of the country. It is of the utmost importance that this material should be got into the soil at an early date. Certain experts have expressed the opinion after a survey of many allotments that on a great deal of allotment ground the crops would have been practically doubled during the past season had it been possible to get the turves which were stacked dug in early in the year. Where allotments were made in late spring this course would not have been practicable, and the turves were accordingly stacked to rot. They should be returned to the land as soon as convenient.

POTATO MAJESTIC.

IN response to Mr. Cuthbertson's request (p. 260, Vol. LXIV.) for growers of Potato Majestic to record their experience with cut seed of this variety I give the following particulars. Last season I purchased $\frac{1}{2}$ cwt. of "seed" as grown, and they were mostly large tubers. Having read Mr. Cuthbertson's lecture recommending this variety, I decided to make as many sets as possible of them, and cut every tuber into as many portions as there were eyes. A few I cut some time before planting, placing the seed in boxes with a slight covering of sifted leaf-mould, and stood them in a late seed-house; the bulk was cut at planting time. They were left till the very last, when I found myself pressed for space, the only available land being ground on which stood several lines of Late May, and June King Broccoli; these had been earthed up, and I decided to plant the Potatos in the bottom of the drills between the rows of Broccoli. I ran a Planet Junior hoe up and down the drills with the cultivating set in the tool frame, merely placing the Potatos in the bottom of the drills, covering each set with a handful of sifted potting soil, with which a little humogen had been mixed. As the Broccoli matured I pulled them up, and as each row was cleared off I earthed the Potatos up with the small plough sent out with the Planet Junior. The old men working in the garden here said I should get no Potatos with such treatment, but, pressed for space and labour, I saw no alternative. I did my best, and left the Potatos to do theirs. When in growth they were a picture, and when lifted yielded a bumper crop; many tubers weighed $1\frac{1}{2}$ lb. each. I cut the seed myself, and took the leading part in planting them, and personally attended to them thereafter. A farmer can hardly expect to succeed with cut seed. The cutting may be carelessly performed, and, with horse cultivation and field planting shoots are apt to get rubbed off; a cut tuber then has little chance of success. I may add the sets were planted some on the 15th and the rest on the 29th of May. *T. A. Summerfield.*

SEED POTATOS.

DURING 1918 the Food Production Department distributed to allotment holders, small-holders, and others in England and Wales 32,000 tons of seed Potatos—13,000 tons being varieties immune from wart disease. In addition 9,200 tons were shipped to the British Expeditionary Forces for planting in France or at Salonica, and 1,600 tons were supplied to the Allied Governments.

ALLOTMENTS.

FIGURES published this week by the Food Production Department showing the expansion of the allotment movement in 1918 are of considerable interest. It appears that up to April 30, 1918, about 31,000 acres of allotments, representing just under 377,000 plots, had been provided under the Cultivation of Lands Orders. Between April 30 and mid-December, 1918, 403 local authorities agreed to acquire 4,370 additional acres, representing nearly 57,000 plots. In the closing weeks of 1918 twelve local authorities decided to lay out a further 154 acres of allotments (2,235 plots).

FRUIT REGISTER.

APPLE EDWARD VII.

APPLE Edward VII. (see fig. 7) proved a most valuable variety in a year noted for a scarcity of fruit. A free and clean grower, it can, on our heavy soil, be depended on to give a good crop of first-grade fruit annually, provided late frosts do not destroy the blossom. So far the variety has proved to be immune from canker and American Blight, which was so prevalent in 1918. The fruit is of a splendid shape, being very regular in outline, and of a good average size. It is coloured yellow, with a tinge of red on the sunny side. The keeping qualities of this Apple cannot be too highly praised, for it ranks with Annie Elizabeth as one of the best very late culinary varieties, useful also as dessert to anyone liking a firm, crisp eating Apple. *John T. Tubb, Bear Wood Gardens, Wokingham.*

tury, who professed to cure every evil under the sun by decoctions of weeds.

The Board of Agriculture, in London, issued a very remarkable leaflet in the autumn of 1914, which indiscriminately advocated the cultivation and collection of all sorts of plants for medicinal use. No serious attempt at a practical classification was made. Prices were given at the market quotations then ruling, which led the reader to imagine that immense fortunes were to be made out of weeds, and it was inferred that no skill or experience were necessary for the cultivation of these plants. Prices were given for ton rates when only hundredweights were required; undried material was confused with dried material; market requirements and cost of package and transport were absolutely ignored. This had a dire result, because throughout the land a large number of people started an indiscriminate campaign of weed collecting, and in consequence manufacturers were inundated with parcels of rubbish. A society was formed

stock and prepare for the purpose of dispensing prescriptions. These books were called *Pharmacopoeias*, and the three volumes were the forerunners of the present-day *British Pharmacopoeia*, which is issued by a conjoint board of the various medical colleges and other kindred associations, and is officially sanctioned by His Majesty's Privy Council. These *Pharmacopoeias* had a far-reaching effect upon the use and manufacture of drugs. All uncertain and doubtful ones were excluded, and only those which according to the knowledge of the period were considered to be reliable, efficacious and potent were included in these publications. The outcast ones were not, however, neglected, for public opinion is always essentially conservative where use and wont are concerned. Their use was continued by a new group of would-be medical curers—the unlicensed and untrained herbalists and quack medicine-mongers who provide the domestic medicine chest and other remedies which are chiefly prepared from herbs.

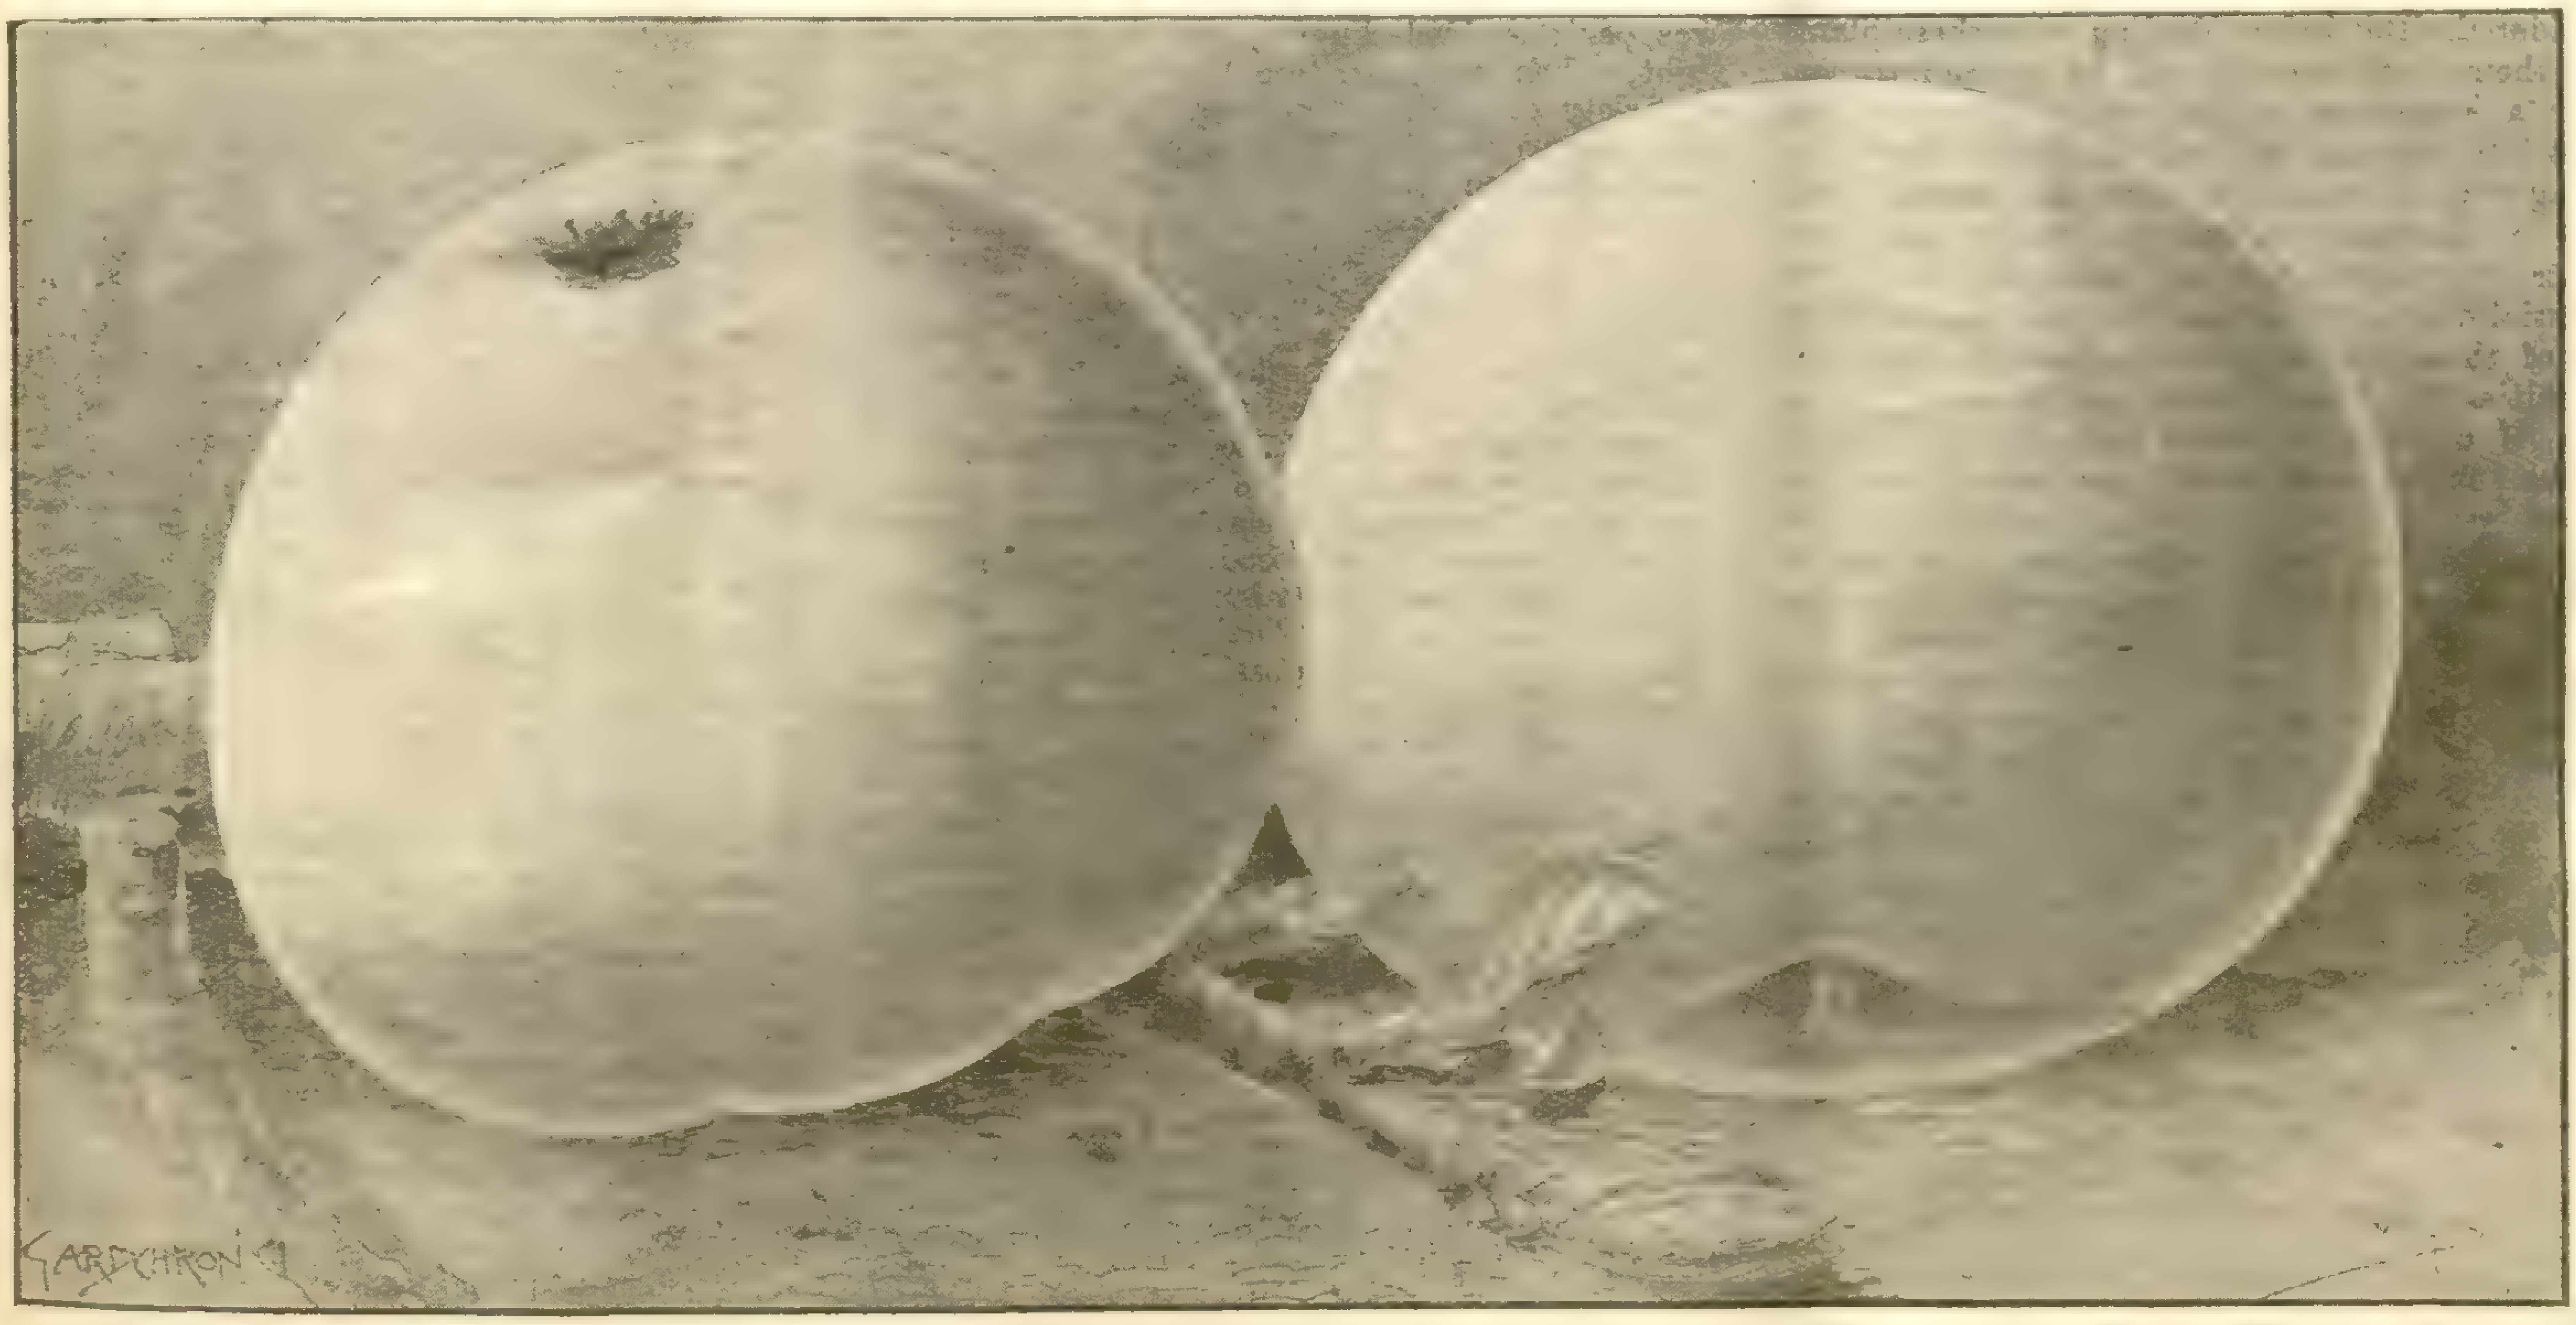

FIG. 7.—APPLE EDWARD VII.; A LATE CULINARY VARIETY.

MEDICINAL PLANTS.*

THE cultivation of medicinal plants has recently become a matter of great interest and distinct importance. Since the commencement of the war the subject has been very prominently brought before the public, but, unfortunately, the position has been incorrectly stated, and a wrong impression as to our present and future needs has been inculcated. A great deal of romance seems to linger round the subject in the minds of many people. Some apparently have poetic visions of delightful gardens of sweet-scented herbs, reminiscent of olden days. Others have conceived the idea that there are practically no drugs to be had, and that medical men are at a loss to find medicines for the alleviation of the sufferings of humanity. All this is totally erroneous, and apparently has arisen through a threatened shortage of a few very important drugs. There is no romance or poetry attached to the work any more than there is to the growing of Potatos. There are quite sufficient drugs in the country, and medical men are not going to revert to the semi-primitive state of the herbalist and quack doctor of the eighteenth cen-

to co-ordinate and organise this rush to the Klondyke of weeddom, and it is to be hoped that the benefit of the experience will lead to success by the natural process of evolution, in which the law of the survival of the fittest will rule, and that out of all this chaos a home industry will become established for the purpose of collecting and preserving the wild plants of our countryside for medicinal purposes.

In order to obtain a correct perspective of this important subject, a brief retrospect must be taken. In the mid-Georgian days the doctor was an apothecary, as well as a physician, and concocted his own medicines, which were largely derived from the vegetable kingdom. In order to obtain these the apothecarian doctor was accustomed to either grow or collect the herbs as his requirements demanded. In process of time, by the development of medical knowledge, both clinical and pharmaceutical, these two branches became separated, and the present-day chemist and druggist came into existence. In consequence of this, doctors had of necessity to state their requirements specifically to the chemist, and ultimately each of the medical corporations, the Royal Colleges of Physicians of London, Edinburgh, and Dublin, drew up and published a book which contained a full description of the drugs and chemicals and their pharmaceutical preparations which the chemist had to

Their use is also continued by that ever-increasing army of patent medicine makers who are continually flaunting their advertisements before the gullible public. A great quantity of herbs are therefore constantly employed in this range of business. The herbs used have been for many years imported from Germany, Belgium, Holland and other Continental countries in immense quantiies, and it was largely due to the lack of the supply of these somewhat questionable drugs that the cry arose about the shortage of medicines when the war broke out, for these quackmongers foresaw that their trade was likely to be seriously endangered. But whilst a large number, in fact the majority, of herbal remedies became confined to the herbalist and patent medicine maker, a comparatively small group of very valuable and important medicinal plants received official recognition by these *Pharmacopoeias*, and by virtue of their incorporation among the official drugs their chemical and medical properties have been most carefully studied, and their use as medicinal agents greatly extended.

For many years farms have existed in England for the cultivation of medicinal plants, notably at Hitchin, Long Melford, Mitcham, and Banbury. These farms are carefully and scientifically managed, and generally they are the properties of manufacturing chemists, so that only the surplus of their raw material is offered on the

* By R. Glode Guyer, Edinburgh. Reprinted from the *Transactions of the Scottish Horticultural Association*, Vol. III., Part 2.

market. Other manufacturers have relied in the past upon another source for the supply of their requirements of raw material for the manufacture of pharmaceutical preparations. This source has hitherto been the Continent—Germany in the vanguard, followed by Belgium, Holland, and France. Germany was a particularly strong supplier, because in that country drug farms are conducted on a large scale, producing immense quantities of raw material for the home manufacturer, and the balance was placed on the open market in London.

From this brief retrospect it will be seen that there are two distinct groups of vegetable drugs which have hitherto been imported, and of which an extended cultivation in this land has been advocated as remunerative and patriotic. One group belongs to those who provide for the requirements of the medical profession; the other is for the quackmonger and patent medicine maker. The former group is the one to which attention is called, and the question of their cultivation and propagation must be rationally considered. But before dealing with these plants and their cultivation it will be as well to consider a somewhat misleading factor which has crept into the problem, and for which the Board of Agriculture pamphlet must be blamed, and that is the inclusion among strictly medicinal plants of herbs which are only used for their essential oils, such as Lavender and Peppermint, and of those plants which are used in enormous quantities for the production of condiments. This is quite a separate and distinct branch of the subject, and should not have been connected with medicinal plants. Essential oils are certainly very widely used in pharmacy, but to only a fraction of the extent to which they are used in perfumery and other manufactures. And likewise with the condiment-producing plants. Here again these are used pharmaceutically, but only a very small proportion of what is produced is required for medicinal purposes. Possibly there may be a great future for such work, and it is a class of work which is quite worth investigation, but when compared with the general consumption their pharmaceutical uses are so small that they cannot be correctly embraced in the category of medical plants any more than Mustard, and therefore cannot be considered in this paper.

(To be continued.)

HOME CORRESPONCENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Silver Leaf Disease (see p. 10).—Mr. Molyneux, writing on Silver Leaf disease in *Gard. Chron.*, Dec. 28, 1918, p. 261, quotes my remark that "It is true that the spores germinate and attack the trees through a wound," and asks "What proof have we of this beyond supposition? Has Mr. Lynch ever detected such wounds, clean at first, watched the inception and progress of the spores in their germination and growth, and seen the result in actual Silver Leaf affection?" A reply is due from me, and I would say that there has been no supposition, that I have seen experimental proof of infection by spores, and that if I had not done so my note would not have appeared. When one has seen a healthy young tree, that was not in the least degree likely to have Silver Leaf disease, inoculated, and within a comparatively short time dead with a development of Stereum, one can hardly fail to believe that Stereum is the cause. But the experiment was not mine, and I am hardly at liberty to refer to it. May I suggest that Mr. Molyneux should do some infecting, using controls of course, and see the result? He would then get a positive result worth more than any number of merely negative results and conclusions, upon which nearly all letters are written. It is a great mistake to suppose that the disappearance of Silver Leaf disease after some particular treatment is any guide to the direct cause. It does not in the least show that Stereum is not the cause, because Silver Leaf disease does disappear of itself, and Mushroom spawn, I believe, has been known to fail. Why not the spawn or mycelium of Stereum? Almost anything might be more or less favoured or discouraged by the alteration of conditions. It is the cause rather than cure that is now in question, but as to cure I have not gathered that any specific can be pointed out from any evidence that has been obtained—nothing, indeed, upon which any reliance could be placed. Mr. Brooks remarks in the same issue that Silver Leaf disease is a general pathological condition which may be induced by various causes, and in my note I could have referred to this view, but preferred to make a clean-cut statement upon what I had myself seen, because from my own experience I should expect that pathological conditions due to different causes would be distinguishable. Mr. Brooks, however, having studied the subject in this connection, may undoubtedly be relied upon. It is conceded, I believe, and for practical purposes it is sufficient, that Stereum is the one cause to be reckoned with, and I have no doubt that we are now in the stage of acceptation that I remember with regard to Potato disease. The cause of Potato disease was perfectly well known, and as clear as daylight, when some writers were still discussing a variety of unnecessary suppositions. I wrote then an article that brought me an interesting communication from the late Mr. Worthington G. Smith, and perhaps for that reason I am interested now in this discussion. Whatever the difficulty was then, the difficulty now is that few people understand anything about wound-fungi. I had rather expected to be taken to task with regard to my suggestion that the fungus Stereum should be exterminated. I believe it would be quite possible if trouble were taken, because the mature Stereum always comes out upon dead wood. In conclusion, I wish to make the suggestion that fruit growers should report to the *Gardeners' Chronicle* at what distance from a possible source of infection they find themselves free or not free from Silver Leaf disease. The spores, - expect, might come from a great distance, but it is possible that at a certain distance the liability to infection might be negligible. A shrubbery should always be regarded with suspicion. A point I do not quite understand is that Silver Leaf disease should be reported as increasingly common, for Stereum has always been common enough. I can only believe that the prevailing weather of the seasons must be an influence, or can it be that more notice of it is taken than formerly? In comparatively recent years we have frequently read of diseases and remedies that were never heard of in the previous period: indeed, a new trade is practically dependent upon them. I cannot believe that the majority of the diseases to which I refer are new, though some are of course. Remedies and explanations were not easy to get, and probably it was that people cut their losses and said nothing. *R. Irwin Lynch, Botanic Garden, Cambridge.*

—— Having read with considerable interest Mr. Bates' remarks (see p. 10) on Silver Leaf disease, it will, I hope, be helpful to readers to know that from experience I find young trees are as equally subject to the disease as old ones. Having planted all the fruit trees in these gardens during the past 12 years, and purchasing them from good nurserymen, none is more than 15 years old; which is not a great age for a fruit tree. The first appearance of Silver Leaf here was on a Royal George Peach planted in the Peach house in the usual way, the border having thorough drainage of about 1 foot of brick ends and similar material. (This tree was also lifted once to check rank growth, so that all chances of a tap-root getting into bad soil were prevented.) I removed diseased branches as soon as detected, but eventually had to grub the tree out. At the same time, Morello Cherries and Plums growing on outside walls in these gardens are badly affected. Of Plums, the variety Victoria is the worst affected. Our soil is a medium loam on calcareous limestone, and in some parts red sand, but in no case can the roots reach clay. I think my experience will show that tap-root and undesirable drainage are not necessarily the causes of Silver Leaf disease; my theory is that the disease is constitutional, and is not so much due to extraneous causes. *F. Spencer, Tockenham Manor Gardens, Wootton Bassett.*

Romneya Coulteri (see p. 10).—Mr. Hicks is doubtful if Romneya Coulteri is worth cultivating because his plant is evidently not growing, but only languishing. Let him dig a hole at least $2\frac{1}{2}$ feet deep and fill it with ashes to within 1 foot of the top, making all firm; then fill the remaining space with earth to which about one-eighth of broken peat and one-quarter of sharp sand has been added, and on this site replant the Romneya early in April. There are two plants of R. Coulteri in a garden between Tunbridge Wells and Pembury that were thus replanted about seven years ago, and now they are quite 3 feet in diameter at the base, and produce scores of blossoms every year. My own plants are not so old as the above, but have flowered freely the last two most unfavourable years, and I know of no summer flower that is more generally admired or more fragrant when cut. In this exposed district the Californian Poppies are usually protected in winter with ashes or Heather, though there is an old plant in the nursery grounds of Messrs. Russell (late Cripps') that flourishes unprotected. With me R. trichocalyx bears a smaller flower than R. Coulteri, but is not noticeably more floriferous. *T. of Kent.*

—— Romneya Coulteri flowers extremely well in my Suffolk garden. Perhaps *T. J.'s* soil does not suit the plant. The soil in my garden is rather light, and I have plants of Romneya 3 yards across, and they are covered with flowers well into the autumn. I counted more than 100 flowers open at one time on one of my plants, and such numbers of the large, white, crinkly blossoms, with their yellow centres, look very effective. My specimens have been planted about ten years, and they continue to throw up new growths and cover more ground each year. I suppose the soil and conditions suit them, as they never receive any special attention. Our climate is probably colder than at Maidenhead, where your correspondent writes from. *C. S. Schreiber, Marlesford Hall, Suffolk.*

The Loss of the Clematis in Gardens (see p. 10).—I have been interested in the correspondence in respect to the failure of the Clematis in gardens. I hold the opinion that the grafting of Clematis has nothing whatever to do with their death. How is it that years ago they did not fail? About 35 years ago I was an assistant in the propagating department of Messrs. G. Jackman and Sons' Nursery, where we propagated Clematis in thousands, both by grafting and cuttings, and I have no recollection of many failures then. The plants were potted as soon as they were ready for transference into $4\frac{1}{2}$-inch pots, and the pots plunged into convenient-sized beds, where the plants seemed to flourish. A grafted plant makes an abundance of roots from the graft in a very short time, and becomes established on its own roots, quite independent of the stock it was grafted upon. Many failures are due to bad planting, and the Clematis often fails where there is a cold subsoil. I am quite ready to admit that during the past 10 to 15 years Clematis have failed, why I do not know. *Henry Havelock, Hastings.*

Nathaniel Powell, Seedsman.—To the *Gardeners' Chronicle* of June 1, 1918, I contributed some notes on a London seedsman of the name of Nathaniel Powell. As neither of the catalogues to which I referred was dated, I was only able to get at the approximate date of Powell's establishment in business from an undated letter of Richard Bradley's, quoted as a sort of testimonial. In recently turning over a large and miscellaneous collection of excerpta on gardening matters, got together many years ago, I came across an interesting advertisement of this same Nathaniel Powell, which I copied from the *County Journal, or Craftsman*, of October 15, 1737. The advertisement runs as follows:—

"TO BE SOLD.

Imported from Holland and Flanders, fine collections of flower roots, viz.:—Fine Tulips, double Hyacinths, fine Turky Ranunculus, Anemonies, with several other sorts, by Nathaniel Powell, seedsman, at the King's Head, near Fetter Lane, in Holbourn, where you may have all sorts of garden seeds, fruit trees, plants, &c."—*W. Roberts, 18, King's Avenue, S.W. 4.*

SOCIETIES.

BIRMINGHAM HORTICULTURAL.

THE annual meeting of the Birmingham Horticultural Society was held on the 31st ult. at the Council House, under the presidency of Mr. E. H. Weaver. The last show promoted by the Society was held in 1914, and it was stated that the balance in hand at the present time amounted to over £438.

Councillor Johnson proposed that a show should be held at Handsworth Park on July 18 and 19, 1919. He said the Society was a Birmingham society, and if the exhibition were held elsewhere there would be great difficulty in getting the material together for the show. It was desirable that after the suspension of operations for so long they should have time to settle down again into working order. No doubt, in the future, the show would be held at different parks of the city, but it would certainly be wise to go to Handsworth in 1919.

Mr. A. R. Brown seconded the resolution, which was carried unanimously.

It was decided to ask the Lord Mayor (Alderman Sir David Brooks) to accept the presidency of the Society for the ensuing year. Councillor Johnson was appointed vice-chairman, Mr. A. H. Brace hon. treasurer, and Mr. L. W. Webster general secretary.

CROPS AND STOCK ON THE HOME FARM.

QUICK HEDGES.

A SUITABLE subject to plant as a fence against cattle is the common Hawthorn or Quick. Well-managed Quick hedges will last in good condition a hundred years. They can either be grown tall or kept dwarf, at will. A good Quick hedge is impenetrable by cattle, and cattle do not eat Thorn, as they do Hazel, Maple, Hornbeam, Beech or Lime. Success depends upon the treatment received. The soil should be trenched 2 feet deep, to allow of rapid and free root action. Trenching prevents stagnation, and yet conserves the moisture in the soil during a spell of summer drought. I may surprise some farmers by urging a liberal addition of manure as trenching proceeds; the more vigorous the growth, the quicker will the hedge be established. Another advantage in a Quick hedge is the small amount of space required, in width, even for a hedge 6 feet high. The hedge need not be more than 1 foot wide, as the main stems are very rigid. Where the soil is naturally dry the hedge can be planted on the level, but where the site is low or wet, or where the hedge is to serve as a boundary on the roadside, a bank 2 feet high should be formed to ensure a ditch to carry off surplus water from the road, field, or garden.

February is a good time to plant Thorn hedges. If possible, the trenching should be done at least a month before planting to enable the soil to settle down. There is a difference of opinion as to the wisdom of planting Quicks in a single, in preference to a double row. I prefer a single row, with the plants 4 inches apart, because I consider a thicker base can be thus obtained than when a double row 10 inches wide is planted. Rake the surface quite level, and cut out a trench sufficiently deep to allow space for the roots. If any roots are fibreless, they should be shortened back to 6 inches, to induce them to make fibres. Place the Quicks quite upright in the trench, cover the roots with fine soil, and tread firmly on both sides. Cut the plants down to within 4 inches of the soil, to induce them to make strong shoots close to the base, because as the foundation is laid so will the future hedge remain. A 2-inch mulch of manure spread on the soil 1 foot wide on each side of the plants during April will arrest the evaporation of moisture from the soil and act as a stimulant as the manure decays. The soil for 1 foot wide at least on each side of the plants should be kept clear of weeds. If the surface is not mulched, stir the soil occasionally. When the new growths are 1 foot high, nip off the tops. Any time during the following winter the growths should be cut back to within 9 inches of their bases; allow an extension of 1 foot the following year. The sides of the hedge should be clipped repeatedly during the summer. Established hedges should be cut at least twice yearly to improve their appearance and induce sturdy growth.

ESTATE MANAGEMENT.

The successful management of an estate of from 100 to 1,000 acres is no easy matter, even to the experienced. There is no universal rule for guidance, as local circumstances in various counties largely govern the methods of procedure. Even in simple things this diversity is apparent; for example, White Oats are in poor demand while black pigs are prime favourites in certain markets.

Numerous books and the weekly notes in agricultural and horticultural journals do much to disseminate useful information to all concerned, whether they are experienced or otherwise, but I feel we should obtain more information from scientists concerning the causes of disease and insect attacks, and how to provide effective cures.

I have long searched in vain for a plain, simple, and effective method of bookkeeping for an estate and farm. At last I mapped out a method of my own, which appears to meet all requirements in a rough and ready way. I allude mainly to the daily sales and the deposit and use of the cash, recorded in a quickly get-at-able manner. Briefly it is this: All sales are entered in a daily diary, to be weekly copied into a ledger under their various headings, Wheat, Sheep, Eggs, Poultry, and Wood of various kinds. In this way the items are easily collected for the annual balance-sheet. All cash is entered in a weekly column account which shows at a glance how the cash is disbursed, i.e., to the bank or in petty cash. A daily diary is kept of all labour; from a cultural point of view this proves instructive, as it shows the time of sowing and reaping certain crops, apart from the opportunity of checking the cost of any crop. The purchases are dealt with under their various headings in the ledger, and collated quite easily. The dairy is dealt with separately, as we have over 200 registered customers for butter alone. I find these accounts are simplified by being kept distinct from those of other parts of the estate.

WOODS.

In the southern counties many of the woods, plantations, and "rows" are in wide belts between fields, or margins by highways planted many years ago, mainly with Hazel. Those who do not know the value of such "rows" would grub them up and cultivate the land, but to the sheep farmer they are valuable, as they provide material for hurdles, while they furnish spars for thatching and many other items of work on a farm.

At one time coppicing was carried out on a large scale in country districts. Thirty years ago much of this wood—Hazel, Ash, Maple and Alder—was largely employed for hoops for sugar and flour casks, and was then remunerative. New methods of importing flour in bags largely reduced the demand for hoops, and coppicing sank to a quite moderate industry. Coppicers then turned their attention to other branches of industry, consequently experts at this work are now very scarce. This means that where hurdle makers are to be found the industry of hurdle making—if well conducted— is quite an interesting phase of estate management. I find there is a brisk demand for many articles made from underwood.

On the Swanmore estate there are at least 200 acres of woods, mainly of Oaks. The undergrowth is of a mixed character, and all useful for some purpose; even Birch is used for broom making. The various woods are arranged in breadths of so many acres, so that each come in rotation for cutting every nine or ten years, according to the growth of the various kinds of wood. Some twenty years ago the underwood was sold to coppicers at the low rate of £2 to £5 per acre, which, for a ten years' growth, was but a poor return. I decided to take the matter in hand as estate work, and from October to June six men are almost regularly employed in the woods. As many as 300 dozen wattled sheep hurdles are made annually, 10,000 faggots or bunts for firewood and for bakeries in the district, Pea stakes in large quantities, rails for fencing, and now that coal is scarce much of the rougher wood is used for firewood, a quantity being quickly cut into a suitable size with a circular saw. Broom making, where Birch grows freely, as it does here, is a profitable occupation, and a handy woodman quickly learns the art. On the whole, the coppicing phase of estate management is very interesting, and certainly remunerative at the present prices for goods that are necessities in rural disricts, especially in counties where sheep are closely folded and early lambs are bred and reared. Wattle hurdles provide more warmth than the ordinary Ash hurdles so largely used in other districts.

I would impress on landowners and the Government, where timber has been largely cut during the past year, the need for replanting to make good the deficiency. If patriotic owners cut timber they should be compelled by law to plant. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

TRADE NOTES.

MR. J. GARDINER, M.P. for Perth and Kinross division, is a leading Scottish Potato grower, and well known in circles connected with the trade.

LIEUT. ROBT. W. ASCROFT has resigned his position as Officer in Charge of Spraying under the Food Production Department, and has joined the Mond Nickel Company, Ltd., with a view to the formation of a special horticultural section of the business. Readers will remember that this company's output of sulphate of copper was at one time commandeered for use in connection with the Food Production Department's Potato spraying campaign.

MR. CHAS. H. CURTIS, Secretary of the British Florists' Federation, informs us that in consequence of numerous enquiries received respecting the possible importation of Gladioli corms from abroad, he wrote the Board of Trade Department of Import Restriction on the subject, and received the following reply:—

SIR,—In reply to your letter of January 1 respecting the importation of Gladioli bulbs from U.S.A. and Holland, I have to say that in the case of both countries the importation is prohibited, and that no concession is being granted in respect thereto.

I regret, therefore, that the answer is in the negative in each case.—Yours faithfully,

C. CAREW ROBINSON,
Deputy Controller.

Obituary.

Mr. George Gordon.—We regret to record the death, at his home in Buccleuch Street, Hawick, on December 30, of Mr. George Gordon, who was formerly gardener at Teviotbank, but retired some time ago.

William Henry Bennett.—The late Mr. William Henry Bennett, of Fowey, Cornwall, whose death was announced on December 10, 1918, was for many years gardener at Menabilly, the residence of the late Jonathan Rashleigh, Esq. Mr. Bennett was formerly employed at the Royal Gardens, Kew, and always spoke of these famous gardens with great affection. During his gardenership at Menabilly, which lasted over many years, he enjoyed the complete confidence of his employer, and was held in the highest esteem by his fellow gardeners in the county of Cornwall and elsewhere. He had a wide knowledge of sub-tropical and hardy plants; indeed, the memory of the late owner is associated with those wonderful Rhododendrons of Sikkim and their many beautiful hybrids, which made the garden famous. The genus Eucalyptus was largely represented, and no notice of the late Mr. Bennett would be complete without reference to the collection of Bamboos that was in his care in the heyday of their popularity. Those of us who knew him personally feel that

we have lost a brother in the profession who had the unfailing traits of a worthy man accompanied with a graciousness to which I gratefully bear testimony. *Harry Williams.*

GARDENING APPOINTMENTS.

Mr. John MacLean, late Gardener at Heathcote, Ilkley, previously for more than 6 years Gardener to Lord KNARESBOROUGH, Kirby Hall, York, and to Lord O'NEILL, Shanes Castle, Antrim, as Gardener to Major COATS, Burrough Hill, Melton Mowbray, Leicestershire. (Thanks for 1s. for R.G.O.F. box. EDS.)

Mr. Andrew Pattinson, previously Gardener to T. G. SHORT, Esq., Ashbrooke Tower, Sunderland, as Gardener to the Marquis of LONDONDERRY, Springfield, Oakham, Rutlandshire.

FIG. 8.—THE MAZE AT BLETCHLEY PARK, BUCKINGHAMSHIRE.

Answers to Correspondents.

AUTUMN SOWN LEEKS: *A. S. T.* Leeks raised in August and planted out in spring with a view to producing large specimens in the following autumn are almost certain to run to seed during the summer. The best results are obtained from sowings made in February in gentle heat, and the plants afterwards grown in a cold frame until the time arrives for planting them in the open.

BROCCOLI: *A. S. T.* Veitch's Self-protecting and Snow's Winter White Broccoli. raised from seed sown in August and treated as you suggest, would prove failures. There are many varieties of late Broccoli which, if planted in good time, will produce heads throughout the spring and up to the end of May, when Cauliflower raised in September and wintered in a cold pit in 4 inch pots should be ready to succeed them. The varieties best suited for this purpose are Magnum Bonum, Early London, and Walcheren.

CANKERED APPLE TREES: *C. M.* The specimens received give ample evidence of a very bad attack of canker (Nectria ditissima). Trees so badly affected should be grubbed out and used for firewood. From specimens not so diseased the cankered branches should be cut out and burned, and the wounds coated with tar. Sometimes it is possible to cut out the diseased portion where a stem is not encircled by canker and the attack is a light one; in such cases the cut surface should be made perfectly smooth with a sharp knife and immediately dressed with tar.

FRUIT FARM PLOUGH: *J. W. M.* Full particulars of the sizes and prices of the fruit farm plough mentioned in *Gard. Chron.* of September 7, 1918, can be obtained on application to Messrs. W. Seabrook and Sons, The Nurseries, Chelmsford.

GAS-LIME AND GAS-LIQUOR: *E. R.* Gas-lime is best used in the garden for the purpose of cleansing the soil from insect pests and other enemies, including club-root disease. On open land 20 cwt. to 30 cwt. of fresh gas-lime per acre makes a good dressing. Spread the lime on the ground and let it remain for ten days or so until it can be broken finely, then dig or fork it in. The sulphide in the gas-lime will kill all pests and weeds, and after certain chemical changes have taken place the sulphide is converted into sulphate of lime, which is a valuable fertiliser. Six weeks should elapse between the application of gas lime and the planting or sowing of the land dressed with it. Fresh gas-lime should not be applied in the manner described to land wherein fruit trees are growing; the land must be fallow. Gas-liquor varies in quality, and its manurial value depends upon its ammonia content, which seldom exceeds 2 per cent. On light soils it has a beneficial effect, especially upon Cabbage crops and swelling fruits, but it must be diluted with from four to six times its bulk of water, or its caustic properties may burn the crops. Grass land may be improved by an application of 100 gallons of gas-liquor, suitably diluted, per acre. Gas-lime should be applied in winter; gas-liquor in spring or summer, according to the crop grown.

GLOXINIAS AND ACHIMENES: *C. C.* If Gloxinia tubers are planted too deeply in the soil the growths may damp off at the base, therefore the upper part of the tuber should be about level with the top of the soil when potting is finished. Achimenes may be planted at once and placed in a house having a temperature of 60°-65°; the old practice of placing the little tubers closely together in boxes of soil and transplanting them in pots or large pans as soon as they have made 2 inches of growth is a good one; ordinary warm greenhouse treatment will suffice after the plants are established in the pans or pots in which they are to flower. The compost should be fairly rich and contain sterilised leaf-mould.

LILIUMS AND HELLEBORES: *C. C.* Place the Liliums in a cool greenhouse or pit where they will receive abundance of light and air; if grown in much warmth and a partially shaded position the growths will be elongated and weak and will not produce flowers satisfactorily. When Hellebores are needed for greenhouse decoration the plants should be lifted and potted carefully as soon as the flower-buds have formed, and placed in a frame or pit, so that the blooms may open clean and be uninjured by slugs. Primulas need very little water during the dull winter season; if over-watered they are liable to damp off at the junction of stem and root.

MAZE AND LABYRINTH PLANS: *G. E. P.* In some old gardening books plans of mazes or labyrinths are frequently given, but they are seldom found in modern works of reference. A plan of a maze on St. Catherine's Hill, Winchester (date 1710), is given in Vol. IV. of the *Standard Encyclopaedia of Horticulture* (Macmillan and Co.), with dimensions. Another plan may be found in *The Formal Garden in England* (Macmillan and Co). The illustration in fig. 8, showing the maze at Bletchley Park, Buckinghamshire, may interest you.

NAMES OF PLANTS: *M. A.* Nephrolepis cordifolia.—*L. R. E.* 1, Jasminum nudiflorum; 2, Strobilanthes Dyerianus; 3, Viburnum Tinus; 4, Galax aphylla.—*M. C. G.* 1, Maxillaria picta; 2, Cypripedium insigne; 3, Quercus Ilex; 4, Geonoma gracilis; 5, Iris unguicularis.

PLANTING SCHEME FOR GEOMETRICAL FLOWER BEDS: *H. T.* We assume that you require the beds to be planted to give a good floral effect in summer, and suggest the following as an appropriate scheme, dealing with the eight beds in pairs as marked on the plan, Nos. 1, 2, 3, and 4:—(1) Lobelia cardinalis Firefly at 1 foot apart, filling the remainder of the two beds with a pink-flowered Ivy-leaved Pelargonium (Geranium) such as Mme. Crousse. (2) Lobelia as in (1), and remainder of beds filled with Calceolaria amplexicaulis, or failing this species, C. Golden Gem. (3) Three standard dark Heliotropes planted equidistant along the middle of each bed; edging of dwarf pink Antirrhinums, and remainder filled with coral-pink intermediate Antirrhinum. (4) Heliotropes as in (3), edging of dwarf orange-red Antirrhinum, and remainder filled with such an intermediate Antirrhinum as Fire King. If young plants of Heliotropes are potted into 6-inch pots now and placed in a warm house, they would become sufficiently large for use by June. All side growths should be removed until the plants are 2 feet 6 inches high, then pinch the top lateral shoots to form balanced heads. The Antirrhinums are easily raised by sowing seed in heat towards the end of the present month. Your clear plan of the flower beds was very helpful in enabling us to furnish a reply.

TENURE OF ALLOTMENTS: *T. W.* Particulars of the tenure of allotments were given in the *Gard. Chron.* of December 14, 1918, p. 234. If an effort is being made to evict you without reasonable notice, compensation may be claimed unless the agreement stipulated otherwise. Copies of the Cultivation of Land Order, and the Allotments Act, can be obtained from H.M. Stationery Office, either direct or through your local bookseller; each costs a few pence. Copies of Orders relating to war-time gardens and allotments may be obtained free on application to the Food Production Department, 72, Victoria Street, Westminster, or the Board of Agriculture, St. James' Square, London, W.

MARKETS.

COVENT GARDEN, January 8.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

	s. d. s. d.		s. d. s. d.
Anemones -		Narcissus, paper white, per doz. bunches ...	3 0- 3 6
— double pink, per doz. bundhes ...	5 0-6 0	— Soleil d'Or, per doz. bun ...	4 0- 6 0
— fulgens, per doz. bunches...	5 0- 6 0	Roses, Safrano, per packet	2 6- 3 6
Mimosa, per pad...	18 0-21 0		

REMARKS.—The supplies from home growers show little change from last week. White Chrysanthemums are sufficient for the demand, and the quality quite good for January. Richardias (Arums) and Lilium longiflorum are advancing in price. Lily-of-the-Valley is arriving in good condition, and is moderate in price. Daffodils are increasing in quantity, and prices are gradually lowering; the principal varieties are Golden Spur and Henry Irving The short supplies are Camellias, Gardenias, and Orchids. Consignments from Guernsey and Scilly are increasing, and arrive here three times a week; these consist of Yellow and White Narcissi, Freesias, Violets, and Smilax; these sell freely at advanced prices. Two large consignments from France arrived last week, consisting mostly of Paper-white Soleil d'Or Narcissi. Anemones, Ranunculus, and Mimosa so far are very few in number, and very few orders can be executed.

REMARKS.—The market is fairly well supplied with black Grapes, and Muscat varieties are available in limited quantities. Forced vegetables include the following:—English and Guernsey Dwarf Beans, Peas, Mushrooms, Seakale, Tomatos, Cucumbers, new Potatos, and Chicory. Forced Rhubarb is plentiful. Grape Fruit from Jamaica is now obtainable. Oranges, including Mandarins, Denias, and Valencias are more plentiful, and there are Lemons from Messina. All seasonable outdoor vegetables are fairly plentiful. *E. H. R., Covent Garden Market, January 8, 1919.*

Continued from page iii.

WANTED, Two young MEN, for Outside; Bothy, vegetables, &c.—Please state wages and particulars to F. T. WOODFIELD, Piggott's Manor Gardens, Letchmore Heath, near Watford.

LADY HEAD GARDENER required; experience in general management essential; four Gardeners kept; Greenhouse for house and Garden plants only.—MRS. T. C. WATERHOUSE, Lomberdale Hall, Derbyshire.

LADY GARDENER wanted; man to help; small place, Belfast.—Apply, D., Box 15, 41, Wellington Street, Covent Garden, W.C. 2.

AN opening for LADY GARDENER, S. Devon (Exmouth), paying guest, with a retired rector and wife.—CENTRAL, 12, The Beacon, Exmouth.

WANTED, married MAN, in high-class young gentlemen's school, with some knowledge of machinery, to run engine for electric light (instruction given), hot-water furnaces, and fill up time in Gardens; wife could be employed in house from time to time; very comfortable quarters, with light and coal. Reply, stating wages and particulars, HEAD GARDENER, Heddon Court, New Barnet, Herts.

HANDY MAN; experienced electric plant, oil engine (Hornsby's), pumps, small car; assist Garden. — Apply, full particulars, ARDERN, Bonishall, Prestbury, Cheshire.

TrADE.

A PROGRESSIVE and well-known Horticultural firm desire the services of a well-educated MAN, primarily as catalogue compiler, for Hardy Shrubs, Plants, and Bulbs, advertisement designer, stock-keeper, &c. Must have up-to-date knowledge of commercial and scientific Horticulture, and be able to correspond on technical trade matters. A good opening for one desiring to associate himself with a go-ahead firm.—Apply, with full particulars, stating salary required, to Box 207, Messrs. W. H. Smith & Son, Kingsway, London, W.C. 2.

YORKSTONE and SKEGNESS SLABBING, for garden paths and paved gardens; only limited quantity; on rail at London. — Apply, YORKSTONE AGENCY, 104, Great Portland Street, W. 1.

JEFFERIES' HYBRID GLADIOLI. English raised and English grown. For massing, few flowers can equal the magnificent display made by our beautiful Hybrid Gladioli, during the months of July, August, and September. Our strain the result of careful hybridising, is altogether superior to the ordinary mixture, usually of Continental origin, offered by the trade. The flowers vary in colour, from pure white, through shades of lemon, yellow, orange, salmon, to deep blood red and purple, the pleasing art shades of orange and salmon predominating.

Secure your bulbs at once; they are scarce, and will be difficult to procure later on.

Strong flowering bulbs, per 100 17s. 6d., per 1,000 £8, carriage free for cash with order.

JOHN JEFFERIES & SON, LTD., Royal Nurseries, Cirencester.

PLANTS, &c., FOR SALE.

SPECIAL OFFER.

FOR IMMEDIATE DISPOSAL

A LARGE TRADE STOCK of ESTABLISHED ORCHIDS, comprising

50 ONCIDIUM ROGERSII, 30s. per dozen.

250 CYPRIPEDIUMS, superior decorative types, hybrids of Leeanum, &c., very good plants, in variety, 42s. per dozen.

100 ODONTOGLOSSUM GRANDE, smart plants, in two sizes, 30s. and 60s. per dozen.

300 CATTLEYA GASKELLIANA, fine plants, in 6in. pots, 2 and 3 leads each, 60s. per dozen.

300 CATTLEYA and LAELIO-CATTLEYAS, HYBRIDS, good plants and useful decorative varieties, in 6in. pots, 48s. per dozen.

500 CATTLEYA and LAELIO-CATTLEYA SEEDLINGS (unflowered), of very choice parentage, purchased from the "Brackenhurst" collection, nice sound plants, mostly in 2in. pots, 20s. per dozen.

2,000 ODONTOGLOSSUM CRISPUM, smart plants, in 4in. and 5in. pots, £12 per 100.

2,000 ODONTOGLOSSUM CRISPUM, nice plants, in 3in. pots, £6 per 100.

5,000 ODONTOGLOSSUM CRISPUM, small plants, healthy and sound, many unflowered, 50s. per 100.

These Od. Crispum are the best type, the famous and beautiful Od. Crispum "Solum," and Od. Crispum "Queen Empress," and others having originated from this stock.

The above is a specially cheap offer, as the plants must be cleared immediately, thus affording a most favourable opportunity to buyers desirous of replenishing stocks, as no importations from abroad are likely to arrive for some time.

Specially favourable terms to large buyers.

Full particulars from and all inquiries to

WANTED, JOURNEYMAN, for Fruit and Plant Houses; also an IMPROVER. Good wages and Bothy; duty extra.—Apply, A. J. EAST, Shipley Hall Gardens, Derby.

WANTED, two JOURNEYMEN, for Inside; good experience in Fruit and Plants. Also MAN for Lawns. Good Bothy. State wages and experience. — C. JENNINGS, Littlegreen Gardens, Petersfield, Hants.

WANTED, single young MAN to groom, assist in Garden and warehouse.—Apply, with full particulars, to A. MAJOR, Blyton, Gainsborough.

LADY HEAD GARDENER required; experience in general management essential; four Gardeners kept; Greenhouse for house and Garden plants only.—MRS. T. C. WATERHOUSE, Lomberdale Hall, Derbyshire.

TRADE.

TRAVELLER required for Horticultural Trade to call on private establishments in the West of England; ex-Service man preferred.—State full particulars as to past experience and wages required, to X., Box 15, 41, Wellington Street, Covent Garden, W.C. 2.

WANTED, for established Canadian Nursery, near Toronto, by middle March; thoroughly experienced PROPAGATOR; Perennials, Hardwoods, Evergreens; wages 750 dollars per year; free cottage, firewood, and garden.—Reply, giving full particulars, experience, references, age, family, &c.—N. S., Box 1, 41, Wellington Street, Covent Garden, W.C. 2.

WANTED, experienced GROWER for Bedding Plants, Tomatos, Chrysanthemums, &c.; also smart MAN for General Nursery work; must have experience in Herbaceous and Alpines. Good wages and permanency to the right men.—CONWAYS, LTD., Nurserymen and Seedsmen, Halifax.

WANTED, a good TREE and SHRUB PLANTER and GROWER, for Nursery and Landscape work. Also GROWER and PROPAGATOR of Alpine and Herbaceous Plants, Nursery. Both must be experienced and hard working.—T. WOOD, 19, Moor Drive, Far Headingley, Leeds.

SITUATIONS VACANT continued on page ix

THE ROYAL VISIT TO SUTTON'S AT READING

From **The Court Circular.**

'BUCKINGHAM PALACE, March 12, 1918.—The King and Queen travelled by special train on the Great Western Railway to Reading this morning, attended by the Dowager Countess of Airlie, Major Reginald Seymour, and the Earl of Cromer. . . . Proceeding to the Royal Seed Establishment of Messrs Sutton & Sons, the King and Queen were received by Mr. Arthur W. Sutton, Mr. Leonard Sutton, Mr. Martin H. F. Sutton, and the Establishment Staff. Mr. C. K. Butler, Divisional Food Commissioner for the Southern Midlands, and Mr. L. Weaver, Director of Supplies, Food Production Department, were in attendance.'

IN THE VEGETABLE SEED ORDER ROOM.

The King has the execution of orders for Food Production Seeds explained to him by Mr. Sutton.

A CORNER OF THE SEED-TESTING LABORATORY.

The King examines the various methods of testing Food Production Seeds for germination and analytical purity.

A PORTION OF THE PEA-PICKING ROOM.

The Queen watches the hand-picking of Garden Peas by women.

From **The Times**, *March 13, 1918.*

'The King and Queen during a Visit to Reading yesterday were able to add to their growing knowledge of the many ways by which the food supplies of the country are maintained. . . . At the establishment of Messrs. Sutton & Sons they were shown how seeds for food production are sent out to the farmer, the gardener, and the allotment cultivator.'

HYBRIDISATION AND CROSS-FERTILISATION OF FLOWERS.

THE raising of new varieties of flowers by cross-breeding is one of the most fascinating pursuits in gardening, and has resulted in the production of many of the finest flowering plants either for cultivation indoors or for the open ground. During the many years of my life that I devoted to the cultivation and improvement of plants, I made numerous experiments in cross-breeding, chiefly with indoor plants, and succeeded in producing new or improved types of flowers that are now cultivated in many gardens. An account of some of my successes and failures in this work may perhaps prove of interest to others desirous of experimenting in this direction.

Hybridising, or cross-fertilising, consists in transferring by artificial means the pollen of one plant to the stigma of another with a view to combining in the resulting offspring the characters of both parents. The term hybridising is used when two distinct species are employed as parents, and the term cross-fertilising when two varieties of the same species are similarly used. From the plant selected as the mother-parent the anthers should be removed before they burst, as, if allowed to remain, the pollen may fall on the stigma and the flower is then self-fertilised, in which case the seedlings would not be likely to differ from the parent plant.

To obtain successful results the pollen should be applied to the stigma when the latter is in a suitable condition to receive it; this may usually be known by the moist appearance of the stigmatic surface, as when the flower is ready for pollination this part secretes a sticky fluid. Some stigmas are lobed and have two or more stigmatic surfaces that are closed together until they are ready for pollination, when they separate and expose the receptive parts to receive the pollen. In such cases the opening of the stigma gives a ready clue to the time for applying the pollen. The pollen should be as dry as possible when used, and the best time to apply it is on a bright and sunny morning when the air is dry. It should be applied to the stigma as lightly as possible, and I have found a small camel-hair brush best to use for the purpose. Pollen may be preserved by being wrapped in soft tissue-paper and kept in a dry place. It should be carefully separated from the anthers to prevent it becoming damp. I have used Hippeastrum pollen preserved in this way with good results after having kept it from three to four weeks, the pollen of Begonia socotrana after it had been gathered and left in the anthers five weeks, and that of the tuberous section of Begonia preserved under similar conditions for three weeks. I cannot say from personal experience what further length of time pollen may be preserved, as the pollen of some kinds of plants will keep longer than that of others. The plant to be crossed should be removed from others of the same genus, otherwise insects or the wind may carry the pollen of other flowers on to the stigma and thus render useless any attempts at hybridising. But this may be prevented by enclosing the female flower in a fine gauze or muslin bag. Bees successfully fertilise flowers when searching for honey by carrying the pollen from one plant to another, and so impregnating the flowers. If the stock of a particular plant has to be kept true it is necessary to have all plants of an inferior kind removed some distance away, or destroyed, otherwise the stock is liable to be impregnated by bees and may become valueless. Ants also will often pollinate flowers. Plants of Anthurium Veitchii and A. Ferrierense grew side by side; the flowers of A. Veitchii were impregnated with pollen of A. Ferrierense by small ants which carried the pollen; from the seed which resulted I raised a fine batch of seedlings which had the appearance of A. Veitchii until the leaves became about 18 inches in length; but when the spathes appeared they gave evidence of a decided cross between the two parents.

It is a notable fact that certain species will give seed much more freely than others of the same genus, as, for example, Begonia socotrana crossed with varieties of the tuberous-rooted section; the latter seeded much more freely than plants of B. socotrana, and therefore they are best to use as the female parents. Cross-fertilisation nearly always infuses fresh life and vigour into both plant and flower, especially when a species can be used as pollen parent. Whenever an opportunity occurred I always procured fresh "blood" for the purpose of cross-breeding. In crossing the Javanese Rhododendrons I found better results were obtained when true species were used than when both parents were from previous crosses. Many of our florist's flowers have been greatly improved in size, vigour, and colour of the flower by the cultivation of only the finest and best. I always found it a good plan to go through a batch of plants and select the best for cross-fertilising and seed-bearing. These I moved away from the others. I found that the stigma will remain receptive for some time if unimpregnated. Only a few flowers on each plant were pollinated; all the others were removed, so as to throw the energies of the plant into those retained.

The fine strains with large flowers and a distinct range of rich and varied colours of such plants as Gloxinia, Streptocarpus, Primula obconica, and others which have become fixed were obtained by selection.

It is much more difficult to cross-pollinate plants belonging to different genera, and when this is attempted those that are nearly allied to each other should be selected. Even closely allied plants cannot always be effectively cross-fertilised, and even when a cross is supposed to be successful it does not always follow that the progeny will give the results expected. For example, I crossed Agapanthus umbellatus with a variety of Hippeastrum; the anthers were taken from the Agapanthus before the flowers were half developed, and the plant placed in a house in the nursery where there was no other Agapanthus. Seeds were produced, and these, when ripe, were sown. About twelve plants were raised and grown on. The foliage of the seedlings certainly looked as though a cross had been obtained, as it much resembled that of the Hippeastrum, but when the plants flowered they all proved true Agapanthus, although they had Hippeastrum-like leaves. Had these flowers been fertilised again with Hippeastrum, probably a difference in the bloom might have been the result, and I have often regretted I did not try again. I crossed Hippeastrum aulicum with Haemanthus cinnabarinus, and thus produced a plant with a distinct bulb and foliage, and very compact and dwarf habit. This kept alive six years and then died without flowering. A bigeneric cross between the Javanese Rhododendron Lord Wolseley and Azalea indica Stella produced two plants; the foliage and corolla of one plant was very much shorter than that in either of the parents, and was a very interesting cross in many ways, but of no commercial value. The sister plant kept alive nine years, but did not exceed 4½ inches in height; it then died without flowering. A most remarkable result was obtained by self-fertilising a seedling Javanese Rhododendron. Amongst a batch flowering for the first time a single flower on a truss was observed to have one anther slightly petaloid. I removed all the other flowers and impregnated the pistil of this flower with the pollen from the anthers on the same flower. About 18 seedlings were raised; five of these produced distinctly double flowers with colours from pure white, rose-pink, fawn tinted with rose, and flesh colour to yellow. From their resemblance to the double flowers of Balsams they were named the Balsamaeflorum Rhododendrons. The other seedlings flowered, and all had a tendency to petaloidy; these were again impregnated, but all the seedlings reverted to single flowered forms with different shades of colour. It does not always follow that when true species are impregnated with their own pollen that the progeny will prove identical with the parent. In several batches of Rhododendron Veitchianum, a white-flowered species from Moulmein, the seedlings varied very much both in habit and vigour, also in the size and form of the flowers, and in many instances were a great improvement on the parent plant. Seedlings of many other plants vary in the same way, whilst others retain their true character when raised from flowers that have been self-fertilised. There is no general rule whether a hybrid will resemble the male or female parent; it may resemble either or be intermediate between both. I made numerous experiments with several species of Begonias; in some cases the hybrids were similar to the female parent, and many took after the male parent; others proved intermediate between both parents. The following resembled the female parent:—

B. socotrana × with Froebelii.
B. Froebelii × with crimson tuberous variety.
B. crimson tuberous × with B. John Heal.
B. Carrieri × with Schmidtii.
B. yellow tuberous × with Davisii.
B. Madame Leonet × with socotrana.
B. Gloire de Jouy × with socotrana.
B. semperflorens × with tuberous variety.
B. s. atropurpurea × with coccinea.
B. semperflorens × with Davisii.
B. Knowsleyana × with semperflorens atropurpurea.
B. Martiana × with rose tuberous.
B. rose tuberous × with Martiana.
B. weltoniensis × with coccinea.
B. yellow tuberous × with Sutherlandii.
B. pink tuberous × with Sutherlandii.
B. yellow tuberous × with octopetala.
B. Dregei × with Pearcei.
B. Davisii × with Sutherlandii.
B. Sutherlandi × with socotrana.

The following resembled the male parent:—

B. socotrana × with Rex variety.
B. scarlet tuberous × with lineata.
B. goëgoënsis × albo coccinea.
B. crimson tuberous × with lineata.
B. Rex × with Burkei.
B. Martiana × with coccinea.
B. socotrana × with white tuberous.
B. Davisii × with Rex variety.

The following were intermediate between two parents:—

B. Froebelii × with crimson tuberous.
B. yellow tuberous × with Froebelii.
B. rose tuberous × with gracilis.
B. Dregei × with Beddomei.
B. Burkei × with Rex variety.

B. Rex variety × with Burkei.

B. Carrieri × with semperflorens atropurpurea.

B. heracleifolia × with coccinea.

B. picta × with Rex variety.

B. Beddomei × with tenera (Thwaitesii).

B. coccinea × with goëgoënsis.

B. Arthur Mallet × with villosa.

B. socotrana × with octopetala.

B. socotrana × with Pearcei.

Five plants of B. geranioides × with five distinct colours of tuberous varieties; seven distinct colours of tuberous varieties × with geranioides.

I produced the new race of winter-flowering Begonias by crossing B. socotrana, a winter-flowering species, with the summer-flowering tuberous varieties. B. socotrana did not serve as a seed-bearing parent so successfully as a pollen parent, and only a few results were obtained. As the pollen parent B. socotrana produced a distinct race of winter-flowering kinds, having large flowers with the brilliant and varied colours of the female parent. These hybrid varieties commence to flower in October and November, and continue onwards during the greater part of the winter. All these hybrids have proved to be sterile in both the male and female organs, therefore they produce no seed, and have to be increased by cuttings.

Of Cinerarias many distinct "breaks" were made in habit, foliage, and colour of the flower, by fertilising the florist's varieties with pollen of Senecio Heritieri and Senecio multiflora, also with Senecio auriculatissimus. I had no success with the opposite crosses. Amongst Anthurium crosses Anthurium Scherzerianum × with album produced fine spotted varieties; A. Ferrierense × with A. Andreanum produced flowers intermediate; A. Andreanum × with Spathiphyllum cornutum (Minahassae) produced creamy-white spathes: A. Ferrierense × with A. Scherzerianum produced some richly-coloured A. Ferrierense. Hippeastrum Leopoldii, a species from Peru, proved to be the forerunner of all the fine forms with breadth of petal and range of colour from deep maroon-crimson, pure white, rose-pink, crimson-scarlet, and other shades of colour we now possess.

The following Primulas, cross-fertilised, all greatly resembled the female parent: P. Cockburniana × with japonica, obconica, kewensis, and Veitchii. P. deflexa × with Cockburniana, Veitchii, and pulverulenta. P. japonica × with deflexa, kewensis, Veitchii, tangutica, and vittata. P. kewensis × with obconica, japonica, and Cockburniana. P. pulverulenta × with tangutica. P. tangutica × with Cockburniana. P. Veitchii × with pulverulenta, vittata, and Cockburniana. P. obconica × with sinensis and kewensis. P. vittata × with deflexa, pulverulenta, japonica, Veitchii, and tangutica.

P. kewensis, that fine hybrid which originated at the Royal Gardens, Kew, did not yield seed for several years, as it only produced what are termed thrum-eyed flowers, but, by continual watching, what is termed a pin-eyed flower was discovered on a whorl. All the other flowers were removed from the plant, and this was impregnated with its own pollen; this produced seed which was sown; the seedlings when in flower gave seed freely. Finer flowers and more vigorous plants are produced from seed than from original plants increased by divisions.

Many other crosses were attempted on allied genera without any satisfactory results.

The following were failures; the majority were pollinated both ways:—

Phyllocactus × Epiphyllum.

Clivia × Hippeastrum.

Vallota purpurea × Nerine.

Hippeastrum × Nerine, Vallota purpurea, Pancratium, Crinum, Sprekelia, and Narcissus.

Agapanthus × Tritoma and Funkia.

Eucharis × Blandfordia, and Hippeastrum.

Amasonia × Clerodendron, Oxera, and Euphorbia.

Euphorbia × Poinsettia.

Richardia × Caladium, Alocasia, Anthurium, Aglaonema, and Dieffenbachia.

Hedychium × Burbidgea, Globba, Curcuma, and Costus.

Kalanchoe flammea × Rochea (Kalosanthes).

Hibiscus × Abutilon, Pavonia, and Malvastrum.

Diplacus × Mimulus.

Bouvardia × Luculia, Ixora, and Manettia.

Brunfelsia (Franciscea) × Browallia.

Tillandsia × Vriesia, Caraguata, Billbergia, and Oechmea.

Streptocarpus × Gloxinia, Gesnera, Didymocarpus, Chirita, and Achimenes.

Impatiens × Balsams.

Boronia × Eriostemon, Crowea and Correa.

Monochaetum × Tibouchina (Lasiandra) and Pleroma.

Burchellia × Mussaenda, and Ixora.

Rondeletia × Lindenia, Bouvardia, and Ixora.

Vallota purpurea × Belladona Lily.

Maurandia × Rhodochiton.

Diplacus × Mimulus, and Lindenbergia.

Gloxinia × Achimenes.

Amphicome Emodi × Incarvillea Delavayi.

Exacum affine, and E. macranthum × Chironia.

Dipladenia × Mandevillea, and Echites.

Elaeocarpus reticulatus × Crinodendron Hookerianum.

Clianthus puneceus × Swainsonia.

Rhododendron Javanese species and hybrids × Himalayan section.

R. arboreum section × Javanese and Himalayan species and hybrids.

R. Himalayan and Javanese section × Azalea indica, A. mollis, and A. sinensis.

R. racemosus × Azalea, and Himalayan and Javanese species and hybrids.

John Heal, V.M.H.

FIG. 9.—BEGONIA SOCOTRANA: FLOWERS BRIGHT ROSE.

FLORISTS' FLOWERS.

DELPHINIUMS.

AMONG the many plants which have been converted from good into superb garden subjects are the Delphiniums, and to this work of improvement V. Lemoine in France, Kelway and Son and Amos Perry in this country have made notable contributions.

As shown by Mr. Amos Perry in his lecture before the Royal Horticultural Society,* selection and hybridisation have brought about the present superb races. Thus King of Delphiniums, which was introduced about 25 years ago, was the result of many years of selection and is still so popular as to be both grown extensively here and also exported to the extent of 15,000 a year by one firm alone. Among the newest Delphiniums are those produced by Lemoine in 1914 by crossing Delphinium elatum and D. fatsiense, a recently introduced Chinese species.

Of species now in cultivation, Mr. Perry mentions D. cardinale as one of the handsomest; he gives praise also to the pale-yellow flowered D. Zalil, introduced from Afghanistan about 1887. For cutting for market D. formosum is grown exclusively, and for the rockery D. cashmerianum is to be recommended. Of the dwarf D. nudicaule (15 inches), with dazzling scarlet flowers, several varieties exist, including D. n. aurantiacum, with orange-yellow, and D. n. purpureum, with deep rose-purple flowers. As our readers are aware,† Forrest has described vividly the beauty of the Delphiniums of the higher Alps of N.W. Yunnan, near the Tibetan frontier, where species range in height from 4 inches to 6 feet and in colour from palest blue to deep, rich purple. Of the dwarf Chinese species Mr. Perry singles out D. likiangense for special praise. It has been established in the Botanic Gardens,

* *Journ. R.H.S.*, May, 1919.

† See *Gardeners' Chronicle*, Sept. 9, 1916.

Edinburgh. The plant is from 12-15 inches high, forms symmetrical tufts of finely divided, glossy green leaves, and bears numerous erect stems each with 3 to 5 light blue flowers.

The annual Larkspurs are garden races of D. Ajacis and D. consolida. The former, the Rocket Larkspur, occurs in tall (3-4 feet) and dwarf (18-24 inches) forms, and shows a wide range of colours.

D. consolida, the branching Larkspur, is no less valuable and late-flowering. Now that borders are being replanted ample provision should be made for including the best of the perennial and annual Larkspurs.

FRUIT REGISTER.

THE "HIMALAYA" BERRY.

Since writing the note on this fruit which was published on p. 205 I have turned up a further reference in the *Deutsche Obstbauzeitung* for 1910, p. 402, by Paul Dapp-Opplingen, which throws a valuable light on the question. He confirms the origin which I quoted in my previous note, and states that the plant from which the seeds were taken was Rubus arenarius, or, popularly, the "Sand Brombeere." The seedling reproduced the mother-plant exactly. The Sand Brombeere is described and figured in *Illustrirtes Handbuch der Obstkunde*, Vol. 2, page 301. It is there stated that the plant is extraordinarily vigorous, making often 20 feet of growth in a year. The figure of the fruits shows a smaller truss than we know in the "Himalaya" Berry, but this is probably due to the fact that the artist had a very limited space at disposal; the descriptions of foliage and other details agree exactly.

It seems probable that "arenarius" is intended for the Rubus Arrhenii of Lange, and if our Rubi specialists can confirm this we shall have run the "Himalaya" Berry to ground at last. *E. A. Bunyard.*

The origin and botanical status of this prolific Blackberry have long been in doubt. In August, 1915, the Fruit Committee of the Royal Horticultural Society awarded this fruit a First-class Certificate after trial at Wisley. The variety was sent to Wisley by Messrs. Laxton Bros. A fruiting branch was sent to Kew with a view to its determination. On comparison with ample dried materials, and with living plants in the bed, it was identified with a form of Rubus villicaulis, Koehler, having a white felted under surface to the leaves, but as there was some doubt as to the real status of the latter a note on the subject was left unfinished. The popular name presumably afforded a clue to the origin of the plant, but it was found that no such Blackberry was known from the Himalayas, and the point was afterwards confirmed by Mr. J. S. Gamble, who has lost no opportunity of collecting and studying the Rubi of the region in question.

Since then two important works have appeared, Focke's *Species Ruborum* and Sudre's *Rubi Europaei*, while a history of the Himalaya berry has been given by A. T. Erwin in Bailey's *Cyclopaedia of Horticulture*. The date is 1915, and we read that the Himalaya berry is an evergreen Blackberry of Asiatic origin that has been widely planted in the last three or four years. It is said to have been introduced by Luther Burbank in the early nineties, the seed having been received by him from an English traveller who secured it from the Himalaya Mountains. This part of the record is probably erroneous, unless, indeed, it had been first introduced from Europe. As to its botanical status, there is a note that Rubus thyrsanthus, Focke, is included in the work because the plant grown in this country as the Himalaya berry is probably referable to it. This record, however, is not at all borne out by comparison. The status of the plant was under investigation from fresh materials when Mr. E. A. Bunyard's interesting note (page 205) appeared, identifying the so-called Himalaya berry with the Blackberry known as "Theodore Reimers." This is a far more likely history, and we may accept the inference that the fruit found its way to America, and there underwent the rechristening that often follows migrations. It is to be hoped that the erroneous name will now be allowed to drop into oblivion. By the way, is it possible to secure a copy of the figure cited for the Kew Library?

There now remains the question of the botanical status of the plant. Focke, in his recent work, says that Rubus villicaulis is a collective species, fluctuating between R. rhamnifolius and R. gratus, and that it is scarcely distinguishable with certainty from an artificial hybrid obtained by him from R. gratus crossed with the pollen of R. bifrons. The last I have not seen, but from the description I suspect it to be identical with R. villicaulis var. incarnatus, which has the leaves white-felted beneath, as in R. bifrons (and as in the Himalaya berry), not green as in typical R. villicaulis. In a previous account he had explained that this hybrid gave perfect fruits, and that he did not know how to distinguish it from true villicaulis. He also asked, "What is the widely distributed villicaulis?" My inference is that R. villicaulis is a hybrid between R. gratus and R. rhamnifolius, and the variety incarnatus another between R. gratus and R. bifrons, and that the two should not have been combined. The latter must therefore retain its original name of R. incarnatus, Muell. We may therefore conclude that the Blackberry under discussion is a hybrid derivative of R. incarnatus, a bush of which was found by Garteninspector Theodore Reimers in a neighbour's garden, in 1889, and was considered so promising that he obtained a few seeds, from one of which this Blackberry was derived, possibly as an improved race. It might, of course, have been a hybrid direct, but had the bush been simply R. gratus or R. bifrons it would probably not have attracted attention, or the difference in the resulting seedling might have been commented upon. However this may be, it is highly probable that this Blackberry is a hybrid, which opens up a wide field of possibilities. *R. A. Rolfe.*

Fig. 10.—Cypripedium John Hartley.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM JOHN HARTLEY.

This fine hybrid (see fig. 10) between Cypripedium Shogun and C. Reginald Young (Hitchinsiae × insigne Harefield Hall) was fully described in *Gard. Chron.*, Dec. 1, 1917, p. 218. The width of the dorsal sepal of the flower sent us measured 3½ inches. The variety was awarded a First-class Certificate at the meeting of the Royal Horticultural Society on December 3, 1918, when shown by John Hartley, Esq., The Knowle, Morley, Yorkshire.

As with most other hybrids the dominance of a form of a distinct species asserts itself, and in this case it is the insigne Harefield Hall parent.

The parentage of C. Shogun (see fig. 11), for

which Sir Geo. Holford was awarded a First-class Certificate, Sept. 27, 1910, was recorded as unknown. When the plant was described in *Gard. Chron.*, Oct. 1, 1910, it was suggested that probably the parentage included C. Dreadnought (Troilus × insigne Harefield Hall), or C. Aeson giganteum (insigne × Druri), and comparison of the two favours the supposition that C. insigne has been a factor in its derivation throughout.

The lower two-thirds of the dorsal sepal in C. John Hartley is pale greenish-yellow, the side and upper part pure white, the central part having dark chocolate-purple blotches and smaller purple spotting at the sides. The broad petals and lip are greenish-yellow tinged, and slightly veined, with purplish-rose.

and fringed at the margin. The colour is light rosy-mauve, the centre of the lip being of a darker tone and having slight mauve lines. The base of the lip is yellow, and branched yellow lines extend to the centre, merging into yellow blotches on each side of the tube.

CATTLEYA DOUAI.

At the close of the year 1918 flowers of this useful, pure white hybrid between Cattleya intertexta (Warneri × Mossiae) and C. Suzanne Hye de Crom (Gaskelliana alba × Mossiae Wageneri) were sent us by Mr. H. T. Pitt, and Dr. Miguel Lacroze, Bryndir, Roehampton. The form of the flowers and soft texture of the segments are similar to those of C. Gaskelliana alba, and no colour appears except a light chrome-yellow disc to the lip. The flowers are fragrant, and their flowering in the depth of winter in the neighbourhood of London points to them being very desirable for decorative purposes when other flowers, and white blooms especially, are scarce.

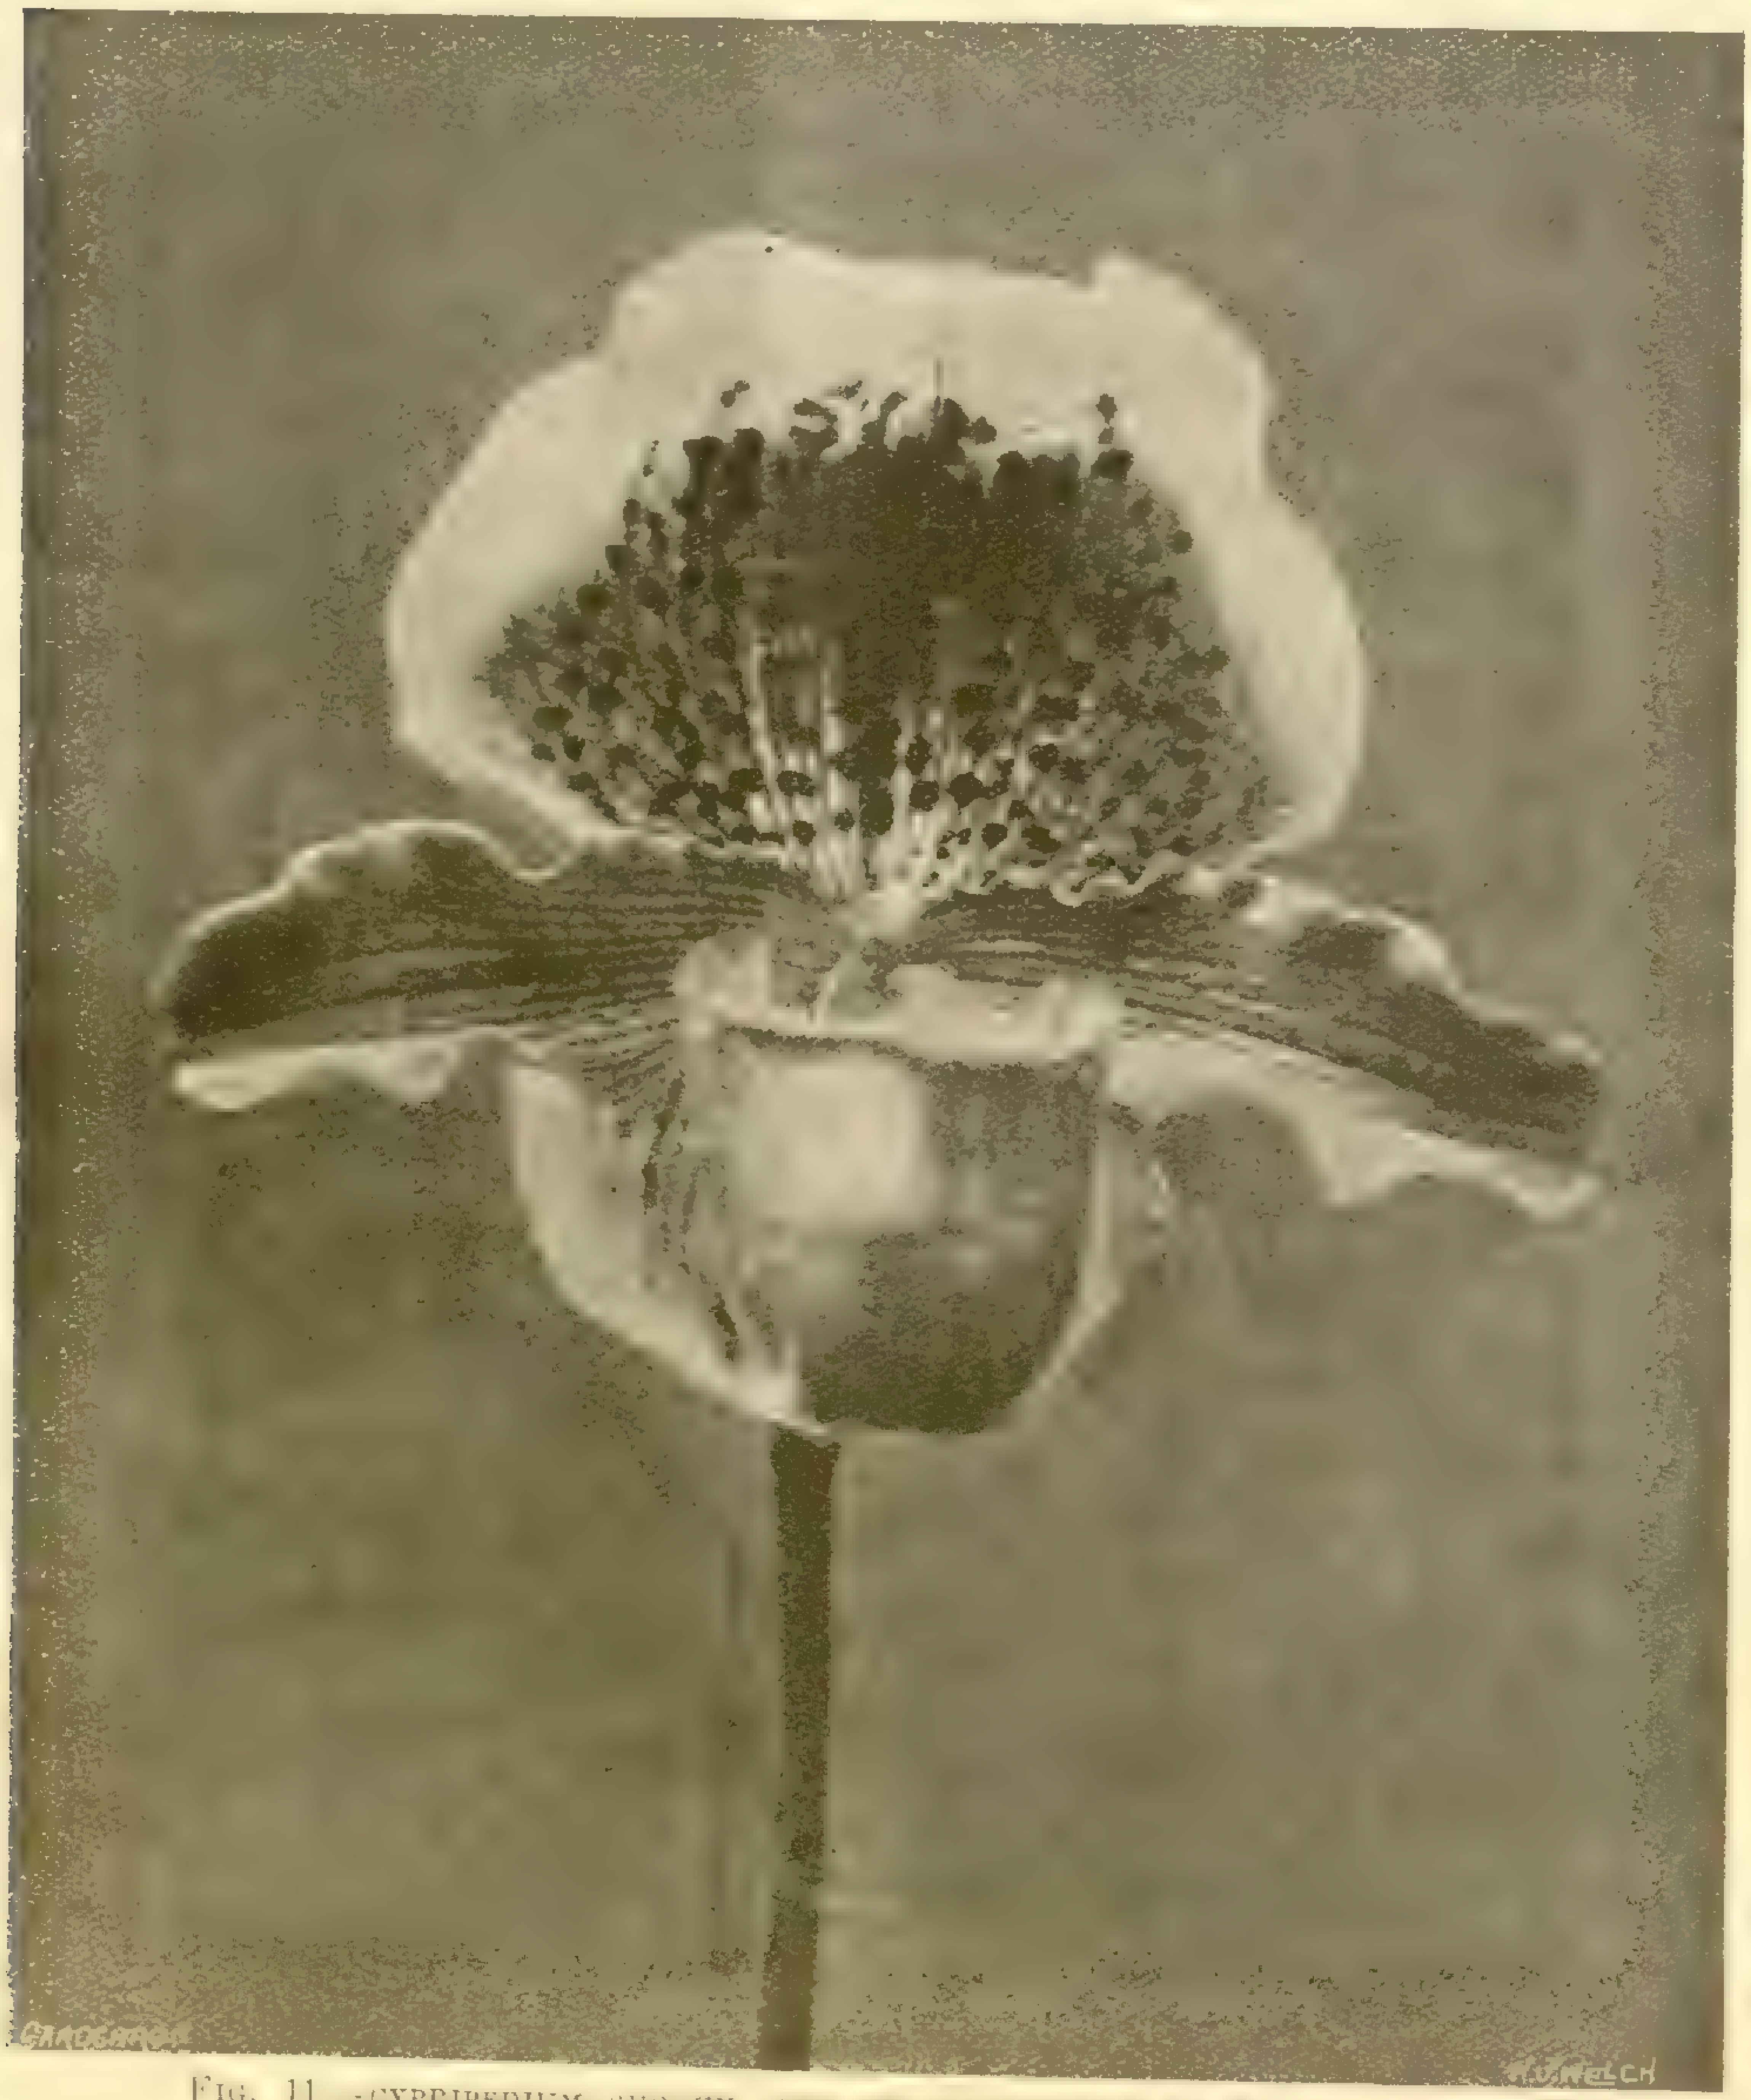

FIG. 11.—CYPRIPEDIUM SHOGUN, ONE OF THE PARENTS OF C. JOHN HARTLEY.

BRASSO-CATTLEYA LLOYD GEORGE.

A noble flower of this new cross between Brasso-Cattleya Marguerite Fournier and Cattleya Lord Rothschild is sent by H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr. Mr. F. W. Thurgood). The flower is of the largest size, ranking with B.-C. Mrs. Francis Wellesley, of which a supplementary illustration was given in *Gard. Chron.*, June 30, 1906, and Sir George Holford's B.-C. The King, which held the record for size and fine proportions.

In the general character the new hybrid resembles the varieties named. The petals extend 9 inches, and are nearly 3 inches in width. The upper sepal is 5 inches and the lower ones 4½ inches wide. The lip is 3 inches wide, crimped

SOPHRO-CATTLEYA FABORIS ROSEBANK VARIETY.

A flower sent us of this variety appears to be the richest in colour of any of the forms of this pretty cross between C. Fabia and S.-C. Doris. The ground colour is rich orange tinged with vinous purple, the lip being ruby-crimson in front and reddish-orange at the base, which bears many branched yellow lines.

The Week's Work.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Lt.-Col. Sir G. L. Holford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Damping.—Damping the houses during the winter is a matter of sufficient importance to justify the most careful attention being paid to it, as at this season most Orchids are in a more or less inactive state. In mild weather, when but a small amount of fire-heat is employed, very little damping is required, while on cold days, when perhaps much fire-heat is needed, more moisture is called for to correct the dryness of the air. At such times the soil beneath the water pipes should be kept thoroughly moistened, but on no account let the water come in contact with the pipes so as to cause vapour to be thrown off, as this is not good for the plants. Damping the bare spaces and walls should be done in the morning when the temperature has commenced to rise, and once a day is usually sufficient at this season.

Preparations for Potting.—It is advisable to obtain a good supply of Sphagnum-moss while the weather remains open, as it sometimes happens at a little later date, when the work of re-potting is daily increasing, the operation is delayed owing to the moss being frozen hard. Also, if obtainable, a good stock of other potting materials should be secured, and a supply of pots, crocks, and other items used in potting cleansed in readiness for the busy season.

Zygopetalum Mackayi.—This is an old, favourite Orchid, and its great merit lies in the fact of its blooming at this season and lasting many weeks in full beauty; it is especially useful where flowers are in demand as cut blooms. The cultivation is not difficult; one of the chief points to observe is cleanliness, as the soft foliage and pseudo-bulbs when young are apt to be attacked by brown scale, a pest which, though easily got rid of, is sure to leave its mark behind after a severe attack. The bloom-spikes appear in the centre of the young growths, and, as the plant is therefore growing and flowering at the same time, considerable moisture is necessary at the roots, even though it is often dull, cold weather at the time. The compost for potting should consist of clean, fibrous loam and leaf-mould, with a liberal addition of coarse sand and finely-broken crocks. The plants dislike being disturbed, and it is important that they be kept in good health, for if once they get into a bad condition they are not easy to bring back to a satisfactory state. Now is the best time, after the flower-spikes have been removed, to renew or add to the compost. The temperature of the Cattleya house suits this Orchid, though a few degrees lower does no harm. The plants need plenty of light throughout the year, and an abundance of water at the roots when in full growth.

THE KITCHEN GARDEN.

By G. Ellwood, Gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Onions.—It has become a recognised rule to raise a goodly portion of the Onion crop under glass, as a great advantage is thereby gained over those sown in the open, the chief points being a longer season of growth, early maturity of the bulbs, and practically no trouble with the Onion fly, which in many districts severely attacks Onions sown in the open. Where large bulbs of the Ailsa Craig type are required, a sowing should be made at once, in boxes for preference. Use a light compost consisting of two parts finely sifted loam, one part leaf-mould, and one part sand. Fill the boxes to within half an inch of the top, press the surface firmly, make it level, and sow the seeds thinly thereon, just covering them with finely-sifted sandy soil. Water the boxes, and place them in a Peach house or vinery that has been recently closed for starting. On no account use an excessive amount of fire-heat.

Cauliflowers.—If seeds of forcing varieties of Cauliflowers were not sown last month, let this be done at once in boxes, using similar soil and adopting similar conditions as advised for Onions. Prick the seedlings off as soon as they are ready for transference, into boxes, at 2 inches apart; at a later date some of the strongest plants may be potted in 2½-inch pots, for an early supply, placing these selected plants in a little more warmth, and repotting them as is needed. The remainder of the seedlings in the boxes should be planted in frames on gentle hot-beds. These plants will be found invaluable, as they will prevent a break in the supply in the late spring should inclement weather occur.

Leeks.—If large plants of Leeks are required for early supplies, sow seed forthwith. In this case, sow the seed in 6-inch pots, filled with light, sandy soil. When the seedlings are ready for pricking off, grow them in a temperature of 50° in a position near the roof-glass. The Lyon and Prizetaker are two first-rate varieties.

Tomatos.—Make a first sowing of Tomato seed where fire-heat is at command; otherwise defer the sowing for a month. Sow in 5-inch or 6-inch pots filled with a moderately sandy compost, just covering the seed; place a sheet of glass or brown paper over the seed pot until the seeds have germinated. Accustom the seedlings to the light gradually, and when they develop the first true leaf, pot them singly in thumb-pots. Grow the plants on a shelf near the roof-glass in a house having a warm temperature. Excess of moisture, both at the roots and overhead, must be guarded against at this season.

Cabbages.—Make a sowing of Cabbage All-heart, Tender and True, and Earliest at various times throughout the year. This plan will do away with the necessity of using autumn-sown varieties for "sprouting." When this system is adopted, ground in which the autumn-sown varieties are grown will be much less exhausted, and ready to receive other crops, such as late Runner Beans and Peas. Heads of autumn-sown Harbinger are ready for cutting here now.

Cucumbers.—Sow seeds of Cucumber singly in small 60-sized pots. Use a light compost that has been warmed. Place the seed pots in an evaporating trough filled with Coconut fibre or leaf-mould. Let the watering be done with extra care until the seeds have germinated.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Figs.—Where very early forcing has to be carried out, pot trees are found to give the best results. The early batch of trees introduced into heat during December will require careful attention, and checks of any kind should be prevented. Disbudding will soon become necessary, or crowding of the shoots will occur later. Keep the centres of the trees open, and stop or remove gross shoots likely to rob the others of their vigour. Stopping should be effected by pinching out the points a few joints beyond the fruits. Afford a temperature of 60° by night and 65° by day, maintain a steady bottom heat of 70° to 75°, and when the temperature has risen to 65° ventilate the house, admitting air in small quantities during mild weather to avoid a stagnant condition of the atmosphere. As growth proceeds, feeding may be resorted to, but applications must not be too frequent or excessive in the early stages of growth.

Successional Trees.—Another batch of trees may now be dealt with. Plunge the pots in a mild hot-bed principally composed of leaves, with a slight admixture of short manure, the whole mixed and sweetened previously. The night temperature should range from 55° to 60°, according to the state of the weather; allow a rise of 10° by day. Ventilate freely on all favourable occasions in order that the trees may grow steadily and make firm shoots. Disbud all badly placed and useless growths as early as possible.

Permanent Fig Trees.—Where the supply of early Figs is produced by established trees the house containing them should be closed forthwith. If the borders are in a moderately moist condition it will not be necessary to water them for some time to come, but on no account must they be allowed to become dry. If water is required, give sufficient to soak the soil to the full depth of the border. Provide a temperature of 50° to 55° at night, and allow an additional 10° by day. When the weather is bright and sunny give the trees a good syringing early in the afternoon when closing the house; damp the borders and paths two or three times a day when the weather conditions are favourable, and admit air freely on similar occasions.

PLANTS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

Carnations.—For the decoration of plant houses under the present restricted controlled system of heating, Carnations in mid-winter contribute the most serviceable, as well as the most economic, type of flower. Flowering plants of Tree Carnations grown in a temperature of 50° to 55° should be watered with care; allow the soil to become moderately dry, then water it sufficiently to moisten it thoroughly, and feed the roots occasionally with a weak solution of a concentrated fertiliser, preferable of Carnation manure. It is essential the plants be kept clean from insect pests by fumigating or spraying. A simple method used by successful growers is to spray the plants occasionally with a weak solution of salt and water. Tree Carnations are best propagated from strong, healthy, clean cuttings, taken at the beginning of October and inserted in a frame previously prepared, with a layer of litter to provide a mild bottom heat, covering the latter with a thin layer of soil and sharp sand. Cuttings rooted in October last, and now in 3-inch pots, should be grown near the roof-glass, watered carefully, and kept free of insect pests. The next potting of these plants should be done with the best procurable loam, mixed with charcoal and Carnation manure. In favourable climatic conditions cuttings of Tree Carnations may be inserted this month. Choose healthy, stout, clean shoots as cuttings, which may be inserted in 3-inch, deep-drained boxes, filled chiefly with sharp sand, or in a prepared bed in a propagating pit having a bottom heat of 60°, and an atmospheric temperature of 55°. They will root in about a fortnight, when they should be potted in 2-inch pots filled with soil containing plenty of leaf-mould, and grown near the roof-glass.

Souvenir de la Malmaison Carnations.—This type of Carnation is suited to the restricted heating conditions, fire-heat being only necessary when the temperature of the house falls below 40°. Even with cool treatment they need an abundance of fresh air. Great care is necessary at this season in watering both young and two-year-old plants. Err rather in keeping the soil dry than too wet. Give two-year-old plants frequent doses of a weak solution of a good fertiliser. The period they are wished to flower will determine the general course of treatment. Keep the growth clean, fumigating or spraying with an insecticide as is necessary.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Black Currants.—The pruning of Black Currants should be done whenever the weather is favourable. As these bushes fruit on the shoots of the previous year, as much of the old wood as can be spared should be cut out, and the young growths retained; in the case of young bushes it is best to allow the terminal buds to remain. Of late years big bud in Black Currants has become a great evil, and, so far as I know, no remedy has been found to eradicate it. The best thing to do is to continue to plant young, vigorous trees, and grub up badly infested ones. If all the big buds are picked off at this season and the bushes dusted with newly slaked lime the pest will be kept in check. The Black Currant needs rich soil, and if planted in a situation that is shaded by a building during the hottest part of the day they will not be so liable to attacks of aphides.

Red and White Currants.—Both the Red and the White Currant fruit on the old wood, and the young side shoots should be shortened to form spurs, allowing the leading growths to extend according to the size of bush required. Red and White Currants are better for having the shoots thinned in summer. Both are excellent fruits for training on north walls, and they may be grown as cordons with one main stem or more. The best method of propagating these Currants is from cuttings; select strong, well-ripened shoots about 12 to 15 inches long, and rub out the buds at the lower end, leaving about seven or eight eyes above ground. In making a trench for planting the cuttings, level the ground with the back of a spade and cut out the soil on the slant, and place the cuttings about 6 inches apart and about 6 inches deep. They are best inserted in the autumn, but they may still be put in; at this late date they will do best in the shade of a north wall. After pruning operations are finished and all suckers removed, apply a good top-dressing of manure to all berry bushes. If animal dung is not available, apply a dressing of bone meal, 3 parts, and kainit, 1 part; if the trees are growing in poor soil, add 2 parts nitrate of potash and give a larger dressing. Common salt is very beneficial to bush fruits growing on light lands, and should be applied in March at the rate of 4 to 5 cwt. per acre, or about 2 ounces spread around each tree. If the bushes are infested with moss or lichens they should be dusted over with quicklime when damp after rain. The lime will not only keep the bushes clean: it also acts as a fertiliser and keeps the soil sweet. Any planting to be done should be completed, if possible, during the next few weeks, and not later than the end of March. The exceptionally wet weather is against operations amongst hardy fruit, but it offers advantages to determine if the land is insufficiently drained. If this is found to be so, attend to the matter, as all fruits need a free drainage.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Bedding Plants.—Make a close examination of bedding plants raised and wintered in cold frames; remove decayed foliage and weeds, and stir the surface soil between the plants. In the case of such comparatively hardy plants as Pentstemons, Pansies, Carnations, Calceolarias and Antirrhinums, remove the lights entirely in mild weather. In cold weather and when keen winds are blowing, regulate the amount of ventilation accordingly, and afford the plants extra protection in very severe weather to prevent the roots and soil from freezing.

Stock Plants.—Where it is intended to employ Fuchsias, Heliotropes, and similar plants for bedding purposes during the coming season, a few plants should be lightly pruned, watered, and brought into gentle warmth for the purpose of obtaining a plentiful supply of strong, healthy shoots suitable for cuttings. The plants propagated from these shoots and grown on should develop into sturdy specimens by the time they are required for planting out in the open. All stock plants should receive careful attention, and the roots supplied with just enough moisture to keep them fresh and the wood plump. Remove decayed foliage on Pelargoniums and other large plants intended for transferring to vases and large pots for standing in the open during the summer.

The Seed Order. — Draw up a list of the seeds required, both for sowing in the open and under glass, and despatch it to the seedsman forthwith. Certain seeds, such as those of Canna and Acacia, with very hard coats, require a long time to germinate, and may be sown at once in a sweet, sandy compost. Stand the seed-pan on or plunge it in a mild hot-bed. Keep the soil only sufficiently moist to assist the seeds to germinate. When the plants are well through the soil transfer them to other pots. If the seeds appear to be germinating irregularly retain the pans in the same position for some time, as frequently some of the best varieties are amongst the last to come up.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.8°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Wednesday, January 15, 10 a.m.: Bar. 29.8; temp. 54°. Weather—Dull.

Partial Soil Sterilisation and Vegetable Production. Lieutenant Truffaut, who has a wide circle of friends among British horticulturists, has been able during the war to turn his expert knowledge of intensive cultivation to good use on behalf of his country. In his capacity of Director of National Nurseries he has had under his charge no fewer than 57 nurseries devoted to the raising of vegetable seedlings for distribution among the 7,000 vegetable gardens now being cultivated by French soldiers. In a recent month these nurseries distributed upwards of 25 million plants for "growing on" in the soldiers' gardens.

In a contribution recently presented to the French Academy of Science, Lieut. Truffaut describes the striking results which he has been able to secure in the seedling nurseries by adopting the practice of partial soil sterilisation. His starting point was the discovery by Russell that partial sterilisation produced by heating soil to 98° C. or by the use of antiseptics, augments the fertility of the soil. Lieut. Truffaut's exepriments have been made with carbon bisulphide as a soil-sterilising agent. In one large-scale experiment he obtained the following results:—

CABBAGE (EXPRESS).

Four rods produced in 90 days:—

In unsterilised soil.	In sterilised soil.
13,684 plants	27,894 plants
Weighing 115 lbs.	302 lbs.

The seedlings raised in the soil treated with carbon bisulphide were remarkably healthy and free from disease.

Yet more interesting, in view of the low price of calcium sulphide, are the results obtained by the use of this substance. A trial with Radish harvested in September-October, 1917, gave the following results:—

	Harvest from 4 rods.	Increase in crop.
Untreated soil..	225 lbs.	—
1.320 lbs. of calcium sulphide	378 lbs.	67%
1.760 ,, ,,	495 lbs.	119%
2.200 ,, ,,	506 lbs.	124%

The calcium sulphide used in this experiment was of 50 per cent. purity.

Similarly with Swedes, the use of pure calcium sulphide as a soil sterilising agent gave remarkable increases in yield. Employed at the rate of one-fifth of an ounce to the square yard, a yield of 187 lbs. per 4 rods was obtained. One ounce per square yard increased the yield to 1,000 lbs. (429 per cent. increase); but it is noteworthy that a larger dose of pure calcium sulphide—namely, just under 2 ounces—per square yard, only led to the relatively small increase of 123 per cent. (418 lbs. per 4 rods).

Similar favourable results have been obtained by Lieut. Truffaut with various subjects—Cabbage, Godetias, and Tomatos—grown in pots.

The fact that an increase of yield was obtained in the case of the Tomato is worthy of the attention of those in charge of the Lea Valley Experiment Station, for if calcium sulphide is so useful a soil sterilising agent, it may prove of economic importance to the growers of Tomatos under glass.

Lieut. Truffaut concludes that the best "dose" in which to employ calcium sulphide is one of 230 to 275 lbs. per acre, spread on the ground in February or March, and forked in. Experiments made by using a sterilising mixture of calcium sulphide and naphthaline gave yet more striking results: in the case of Swedes an increase of yield over that of the control plot of 511 per cent.

Honour for Lord Lambourne. — Horticulturists will learn with pleasure that Lord LAMBOURNE, of Bishop's Hall, Romford, has been appointed Lord-Lieutenant of the County of Essex.

Peerage for the Rt. Hon. R. E. Prothero.—We understand that the Rt. Hon. R. E. PROTHERO, who so ably filled the post of President of the Board of Agriculture during the war, in the Coalition Government, is to be honoured with a peerage. His abilities in the late Administration have been recognised by his appointment as President of the Board of Agriculture in the new Government.

British Gardeners in Belgium Under the German Occupation.—Messrs. G. E. CLARKE and ALFRED R. CUMMINS, who have during the past eight years been head and second gardeners respectively in the employ of Monsieur R. PAUWELS, at Everberg, Belgium, have reached their respective homes in Reading and Croydon. Everberg is situated between Brussels and Louvain, and during the war Messrs. CLARKE and CUMMINS experienced many hardships. They were made prisoners by the Germans in 1915, and interned in Brussels for three weeks, eventually being released on parole to follow their employment, having to report regularly twice a week at a German depot in Cortenberg, and on certain dates in Louvain, the Germans frequently giving surprise visits during the night. Owing to shortage of fuel Orchids and other valuable and tender plants were ruined, but all the glasshouses were used for growing vegetables and fruit, and by intensive culture in the kitchen garden they were able to grow—and hide from the Germans—large quantities of produce, much of which went to Belgian people less fortunately placed than themselves.

Land for Soldiers.—According to the Parliamentary Correspondent of *The Times*, it is understood that a Government Bill to provide land for soldier settlers is now ready, and that it will be introduced soon after the assembling of the new Parliament. It will introduce a new system of land acquisition. Power will be given for the public acquisition of land in exchange for an annuity to the present owner, the State having the right at any time to redeem the annuity by awarding Consolidated Stock sufficient to produce a like annual sum. The small holdings committees of the County Councils will be charged with the duty of ascertaining what land is required, and the Board of Agriculture will have power to act in default. The responsibility for acquiring land will rest with the county councils, and again the Board of Agriculture will have power to act in default. Soldiers wanting land will be required to make application to the small holdings committees of the county councils. The former plan of farm colonies has been discarded, and men wanting land are to be given it as near their old homes as possible. The County Councils will be responsible for providing the necessary housing accommodation and farm buildings. Schemes are being prepared for establishing systems of co-operative credit, for furnishing loans to settlers for the purchase of farm implements, etc., for encouraging rural industries, and for village reconstruction generally.

Flowers in Season. — Some very finely flowered branches of Acacia Baileyana and A. decurrens have been sent us by Mr. G. SMITH, Elmers Court Gardens, Lymington, Hampshire. Mr. SMITH informs us that the flowers were cut from plants growing in the open at Lymington, and he writes: "With reference to *W. W.*'s recent 'Notes from Kew' regarding the hardiness of Acacia Baileyana, this species seems to be equally as hardy here as A. decurrens. Both species were planted out in a sheltered position eight years ago, and the specimens are now about 15 feet high and are almost as much through."

Waste Lime.—According to the "Monthly Notes on Manures" issued from the Rothamsted Experimental Station, recent tests have shown that the residues from calcium carbide used to generate acetylene are perfectly safe for application, and constitute a useful source of lime to allotment holders and small consumers. In the fresh state the lime is distinctly wet, but the excess of liquor rapidly drains away, and the lime becomes more or less friable. It may be applied to allotment land at the rate of ½ cwt. per rod now, or within the next few weeks, and left exposed to rain or any frost that may come; later, when it is broken up, it may be worked into the soil. If sufficient waste lime from any source is available it may be used in similar manner—put on at once, left to disintegrate in winter, and harrowed in in spring. A grower purchasing waste lime, however, should always do so on analysis, as otherwise he may be paying more than would be asked for an equal quantity of fresh lime. So far as can be gathered, lime from magnesian limestone appears to answer satisfactorily on heavy soils, but is liable to cause trouble on light soils.

Allotments Organisation in Greater London.—The Agricultural Organisation Society has instituted a Special London District Allotments Committee, representative of organised allotment holders, to assist allotment holders within a fifteen mile radius of Charing Cross to organise themselves into properly constituted Associations, with powers to rent land on lease, sub-let to members as allotments, and to purchase members' seeds, seed Potatos, and other requirements on the best possible terms. An organiser, who is to devote the whole of his time to this work, has been appointed.

National Seed Testing. — At the National Seed Testing Station attached to the Food Production Department, 14,569 samples of seeds were tested in the year 1918. During the first five months of the station's second season, namely, August 1, 1918, to December 31, 1918, 8,185 samples were tested. Of these, 3,397 samples were Wheat; 784 samples were Oats. This season Peas and vegetable seeds are being received in far greater quantity than last sea-

Rely on Ryders

That was the watchword of allotment holders and gardeners for 1918—Rely on Ryders.

The past Season proved the wisdom of the watchword. Results were the criterion of the quality of Ryders Seeds.

No efforts have been spared by Ryders organisation to make the coming season's supplies worthy of their high reputation for quality.

Ryders Seeds still at 1½d. per packet.

You can again "Rely on Ryders," confident that your trust in the quality of Ryders Seeds will be completely justified. Orders should be sent early. The demand will be greater than ever.

COMPETITION 1919.

Ryders 1918 Competition was an overwhelming success. The results were so encouraging that an extended competition will be open in 1919. Prizes are to be increased to three awards (1st, 2nd and 3rd) in every class. Make sure you enter.

Send a postcard to-day for a copy — of the 1919 Catalogue. —

SALES BY AUCTION.

WEDNESDAY NEXT.

1,000 Rose Trees, 500 Fruit Trees and Bushes, named Rhododendrons, Herbaceous Plants, and Spring-flowering Bulbs.

MESSRS. PROTHEROE & MORRIS will sell the above at their Central Sale Rooms, 67 and 68, Cheapside, London, E.C.,

On Wednesday, January 22nd, at 1 o'clock

Catalogues had. Commissions executed.

HANWORTH, near FELTHAM, MIDDLESEX.

Re Thomas S. Ware (1902), Ltd.

In the High Court of Justice.

CLEARANCE SALE.

Large quantities of Begonias, including Ware's celebrated collection of named double varieties, the collection of Dahlias, several lots of Herbaceous Plants.

Several hundred lights.

Tools, Utensils, Office Furniture, Seed Drawers, and Seed Shop Fittings, Flower Pots, Vans, and Sundries.

MESSRS. PROTHEROE & MORRIS, having disposed of the Freehold Estate, will sell the above by auction on the premises

On Monday and Tuesday, February 3rd and 4th, at 12 o'clock each day.

May be viewed one week prior to sale. Catalogues had on the premises of Messrs. Dawson & Co., Solicitors, 2, New Square, W.C.2; F. Hyland, Esq., the Receiver (Messrs. Hyland & Riches), Accountants, 81, Cannon Street, E.C.4; and of the Auctioneers and Valuers, 67 and 68, Cheapside, E.C.2.

LANCING.

Six well-built Greenhouses, each about 100 feet in length, containing 15,000 feet of glass and woodwork, glass mostly 16 x 20 size, 2,170 feet 4-inch piping, guttering, three boilers, Peach Trees and Vines.

MESSRS. PROTHEROE & MORRIS will sell the above by Auction on the premises,

The Nursery adjoining West House, North Lancing,

On Tuesday, January 21st, at 2 o'clock,

in lots, by order of F. P. Wilson, Esq.

May be viewed one week prior to sale.

Catalogues of Mr. Aldridge, The Gardener at West House, and of the Auctioneers, 67 and 68, Cheapside, E.C.2.

CHRYSANTHEMUMS

The celebrations of the Anniversary of Armistice Day, November 11, will in future years cause a bigger demand for flowers than has previously been experienced.

The Chrysanthemum will be the leading feature for supplying the demand, and will be at their best at that time.

We have Large Stocks of the very best sorts for all purposes. Write for our List or advice, or let us know your requirements. Plants in February or March, suitable for this or any other period of flowering, **5s.** per dozen. or **30s.** per **100**, our selection.

Our stocks of the leading Japanese, Incurved, Decorative, Single and Early-flowering varieties are well up to our usual standard, but in view of the enormous demand orders should be given now.

We are also able to supply, from March, the best varieties of Perpetual Carnations in thumb pots, at **15s.** per dozen, **£5** per **100.**

DICKSON'S "HAWLMARK" ROSE TREES.

Alex. DICKSON & SONS, Ltd., "Hawlmark," Newtownards, Co. Down.

Winter Washing, Spring & Summer Spraying

VARIETY DUMELOW'S SEEDLING.

THE AVERAGE APPLE CROP for 1918 was one of the worst on record. In many districts there was a good set of fruit, and most crops could have been saved had the trees been properly sprayed in time with Nicotine Liquid Insecticide, and the foliage saved from destruction. The above is a photograph representing an average tree in a large plot of young apples grown by the advertiser. The 1918 crop is the finest produced since the trees were planted. Success is entirely attributed to Winter Washing, followed up during the growing season by several sprayings with "XL ALL" Liquid Insecticide, used 1 40 parts of water, the cost per tree being 6½d. for materials. (The cost of spraying will be higher for next season, as the Nicotine Liquid has advanced in price.) The first spraying took place just before the bloom commenced to open, in fact some blossoms were already open. The second spraying was carried out immediately the fruit was set. A third spraying was applied to individual trees and parts of trees where found necessary. The trees were attacked by Black and Green Fly, Apple Sucker, and Caterpillars, and all were soon brought into subjection and destroyed by the Nicotine Wash. Each time the Nicotine Solution was applied, the foliage appeared to improve in colour and substance. The above tree carried splendid Apples, not a single grubby or scabby one. Number of fruit, 102. Weight of fruit, 40 lb. Size of tree: Height, 5 ft. 9 in.; width, 5 ft. 10 in. Considerable thinning was necessary, soon after setting took place, to reduce the crop of fruit to the number here stated.

Particulars of other varieties which carried splendid crops of fine fruit :—

	Number of Apples.	Weight.	
Lane's Prince Albert ..	98	60 lb.	on 5 Cordon Trees, 7 ft. long.

	Number of Apples.	Weight.	Height of Tree.	Width.
King Pippin	160	48 lb.	5 ft. 6 in.	4 ft.
Bramley's Seedling ..	86	40 lb.	5 ft. 6 in.	5 ft. 9 in.
Newton Wonder	105	37 lb.	4 ft. 6 in.	6 ft.

Many other varieties also carried fine crops. All fruits are keeping well!

There is no reason why other Growers who got a good set of fruit this Spring should not have secured similar success had spraying been properly carried out. The remedy was available and only required to be properly used at the right time.

Richards' "XL ALL" Winter Wash: In 1-lb. and 28-lb. tins.

"XL ALL" Nicotine Liquid Insecticide: In 1-pt. bottles; quart, ½- and 1-gallon tins; and 4-gallon drums.

Order through your Nurseryman, Seedsman, Florist, or Sundriesman.

Send for Price List and name and address of nearest Agent.

NOW IS THE TIME TO PLANT PAEONIES

The War is over and we have kept our stock intact, although many other plants have ceased to exist in our Nurseries owing to the withdrawal of labour. There is no plant so satisfactory as the PAEONY to plant for permanence in a garden. It is essentially perennial and hard to kill by neglect.

The plants we are now offering, owing to the War, are larger than usual and full of bud, and planted now should be in good flowering state next year and for many years to come.

We offer Collections, chiefly English varieties raised in our Nurseries, and comprising all the various colours, strong as well as delicate, for which the Paeony is celebrated.

COLLECTIONS OF KELWAY'S LOVELY HERBACEOUS PAEONIES.

Named Varieties, as advertised, the selection of sorts being left to Kelway and Son.

COLLECTION "A," 21/- per dozen, 2/- per plant net, old named kinds of the commoner colour.

COLLECTION "B," 27/- per dozen, 2/6 per plant net, fine old named kinds, with a wider range of colour.

COLLECTION "C," 36/- per dozen, 3/- per plant net, more recent kinds and the best of the older varieties, and fragrant sorts.

COLLECTION "D," 54/- per dozen, 5/- per plant net, more recent kinds in the most delicate tints and most fragrant sorts.

COLLECTION "E," 70/- per dozen, 6/- per plant net, very recent novelties of finest form and most enchanting colours and fragrance.

COLLECTION "F," 90/- per dozen, 7/6 per plant net, Cream of the collection.

NOT LESS THAN 12 AT THESE PRICES.

LISTS ON APPLICATION

son. As showing the popularity with the trade already obtained by the station, it may be mentioned that upwards of 160 seed firms have opened deposit accounts.

Soldiers as Fruit Pruners.—Under the supervision of the Horticultural Instructor for Somerset soldiers are being utilised in that county for the pruning of orchards, after receiving a period of expert training. The work costs about £1 per acre; 28 acres have been finished; 24 acres are now in process of being pruned; and orders have been received for the pruning of a further 30 acres. The work is said to have been most satisfactorily performed.

Basic Slag Supplies.—The demand for basic slag by growers in England and Wales is unprecedented at present. Deliveries so far are 16 per cent. above those for the same period last year. Those who have not yet been able to obtain their supplies are assured by the Food Production Department that the makers—who have far more orders in hand than they can execute immediately—are doing their best to meet the needs of the situation.

Tomato Production in the United States in 1918.—It is estimated that 18,762,000 cases of Tomatos were packed for commercial purposes by the United States growers in 1918; this amount compares favourably with 14,789,000 cases packed in 1917. In the latter year 672,207 tons of Tomatos were used for canning, as against 852,840 tons in 1918, while the amount used by manufacturers for pulp, puree, and soup in 1917 was 224,069 tons, and in 1918 545,035 tons.

Mr. Frank Reader.—The many friends of Mr. Frank Reader, the popular cashier of the Royal Horticultural Society, will be glad to know he has returned to business at Vincent Square, after a brief illness due to severe strain. As in so many other establishments the staff at the R.H.S. has been depleted during the war, and heavier responsibility has consequently fallen upon those remaining.

Injection of Plants. — Experiments performed by Yasutaro Yendo at the College of Science, Tokio, appear to promise results of the highest importance to horticulturists. While recognising the impossibility of applying methods of injection to plants as effectively as can be done with animals, the author believes* that if particular chemical substances could be made to circulate in a certain measure through the body of plants, it might be possible to stimulate their development, to cure them of diseases, or render them immune to diseases. A large number of widely different species were injected with dilute aqueous solutions of lithium nitrate, copper sulphate, eosin or aniline violet, the best results being obtained from the first two salts. The injected solutions were conducted chiefly through the vascular bundles, but to a less extent through other tissues, the current being mainly in an upward direction; there was, however, a considerable downward current, while transverse conduction was distinctly perceptible. At the end of the experiments the injected substances were found in greatest quantity in the leaves and other organs where transpiration was most active. These results are especially interesting in view of the discoveries made also by E. F. Smith, of the U.S. Department of Agriculture, that galls and other abnormal outgrowths found on plants are due "to an increase in the osmotic pressure due to the heaping up locally of various substances excreted by bacteria." In this case it was found possible to induce small outgrowths by artificial inoculation without the intervention of bacteria. It seems highly probable that further investigations on the same lines may lead to new methods of dealing with plant-diseases, and of promoting normal development, two points of the highest importance at the present time.

(2) "Mechanism of Overgrowth in Plants," *Proceedings of American Philosophical Society, Philadelphia*, Vol. LVI., Art. 6.

Pinguiculas.—The Mexican Pinguiculas appear to be larger flowered than those of other countries. The best of them is P. caudata, which was introduced by Messrs. Sander and Sons, St. Albans, in 1881, and is now fairly common, Orchid breeders growing it in quantity in their seedling houses as a fly-trap to keep down certain midges which lay their eggs on the tiny seedlings, the maggots hatched therefrom being capable of much destruction. Apart from this value the plant has a strong claim to favour in the beauty of its flowers. Next to it, so far as they are known in cultivation, comes P. Rosei, named after Dr. Rose, of Washington, who sent plants of the species to Kew, which flowered in 1911. It differs from P. caudata in having violet-purple, almost blue flowers, and there are other differences. The photograph reproduced in fig. 12 shows P. Rosei as it flowers at Kew, where it is grown in the Cattleya house, and blooms continuously in summer. In winter the leaves assume a different character: they become small, and are arranged in a close rosette, like a little cone, which is the resting condition of the plant. Mr. Elwes, in a note on Mexican Pinguiculas, published in *Gard. Chron.*, May 13, 1911, p. 292, refers to this winter condition, which appears to be usual with the several species mentioned. He found one growing in Mexico at 8,000 feet, "in dry, volcanic sand, on sunny banks outside the forest," the leaves of which had formed a small, close rosette, which was dried up to the size of a Cherry; he sent some examples home by post. No doubt the dry, volcanic sand was wet enough when the plants were in active growth. At all events, Sphagnum-moss and plenty of moisture are what these plants enjoy in this country. There was formerly a handsome yellow-flowered species at Kew, viz., P. lutea, which came from Mexico, but it no longer exists there. Another remarkable species, P. gypsicola, also Mexican, with linear summer leaves suggesting Drosophyllum, and winter leaves like a little Saxifraga, flowered at Kew about five years ago, when hybrids between it and P. caudata were raised, but it has been lost, perhaps because it could not have a wet gypsum rock to grow upon, as it is said to do in nature. P. Rosei is quite easy to cultivate, and it multiplies itself by means of offsets formed about the crown. These plants can also be propagated from leaves, as in the case of Begonias.

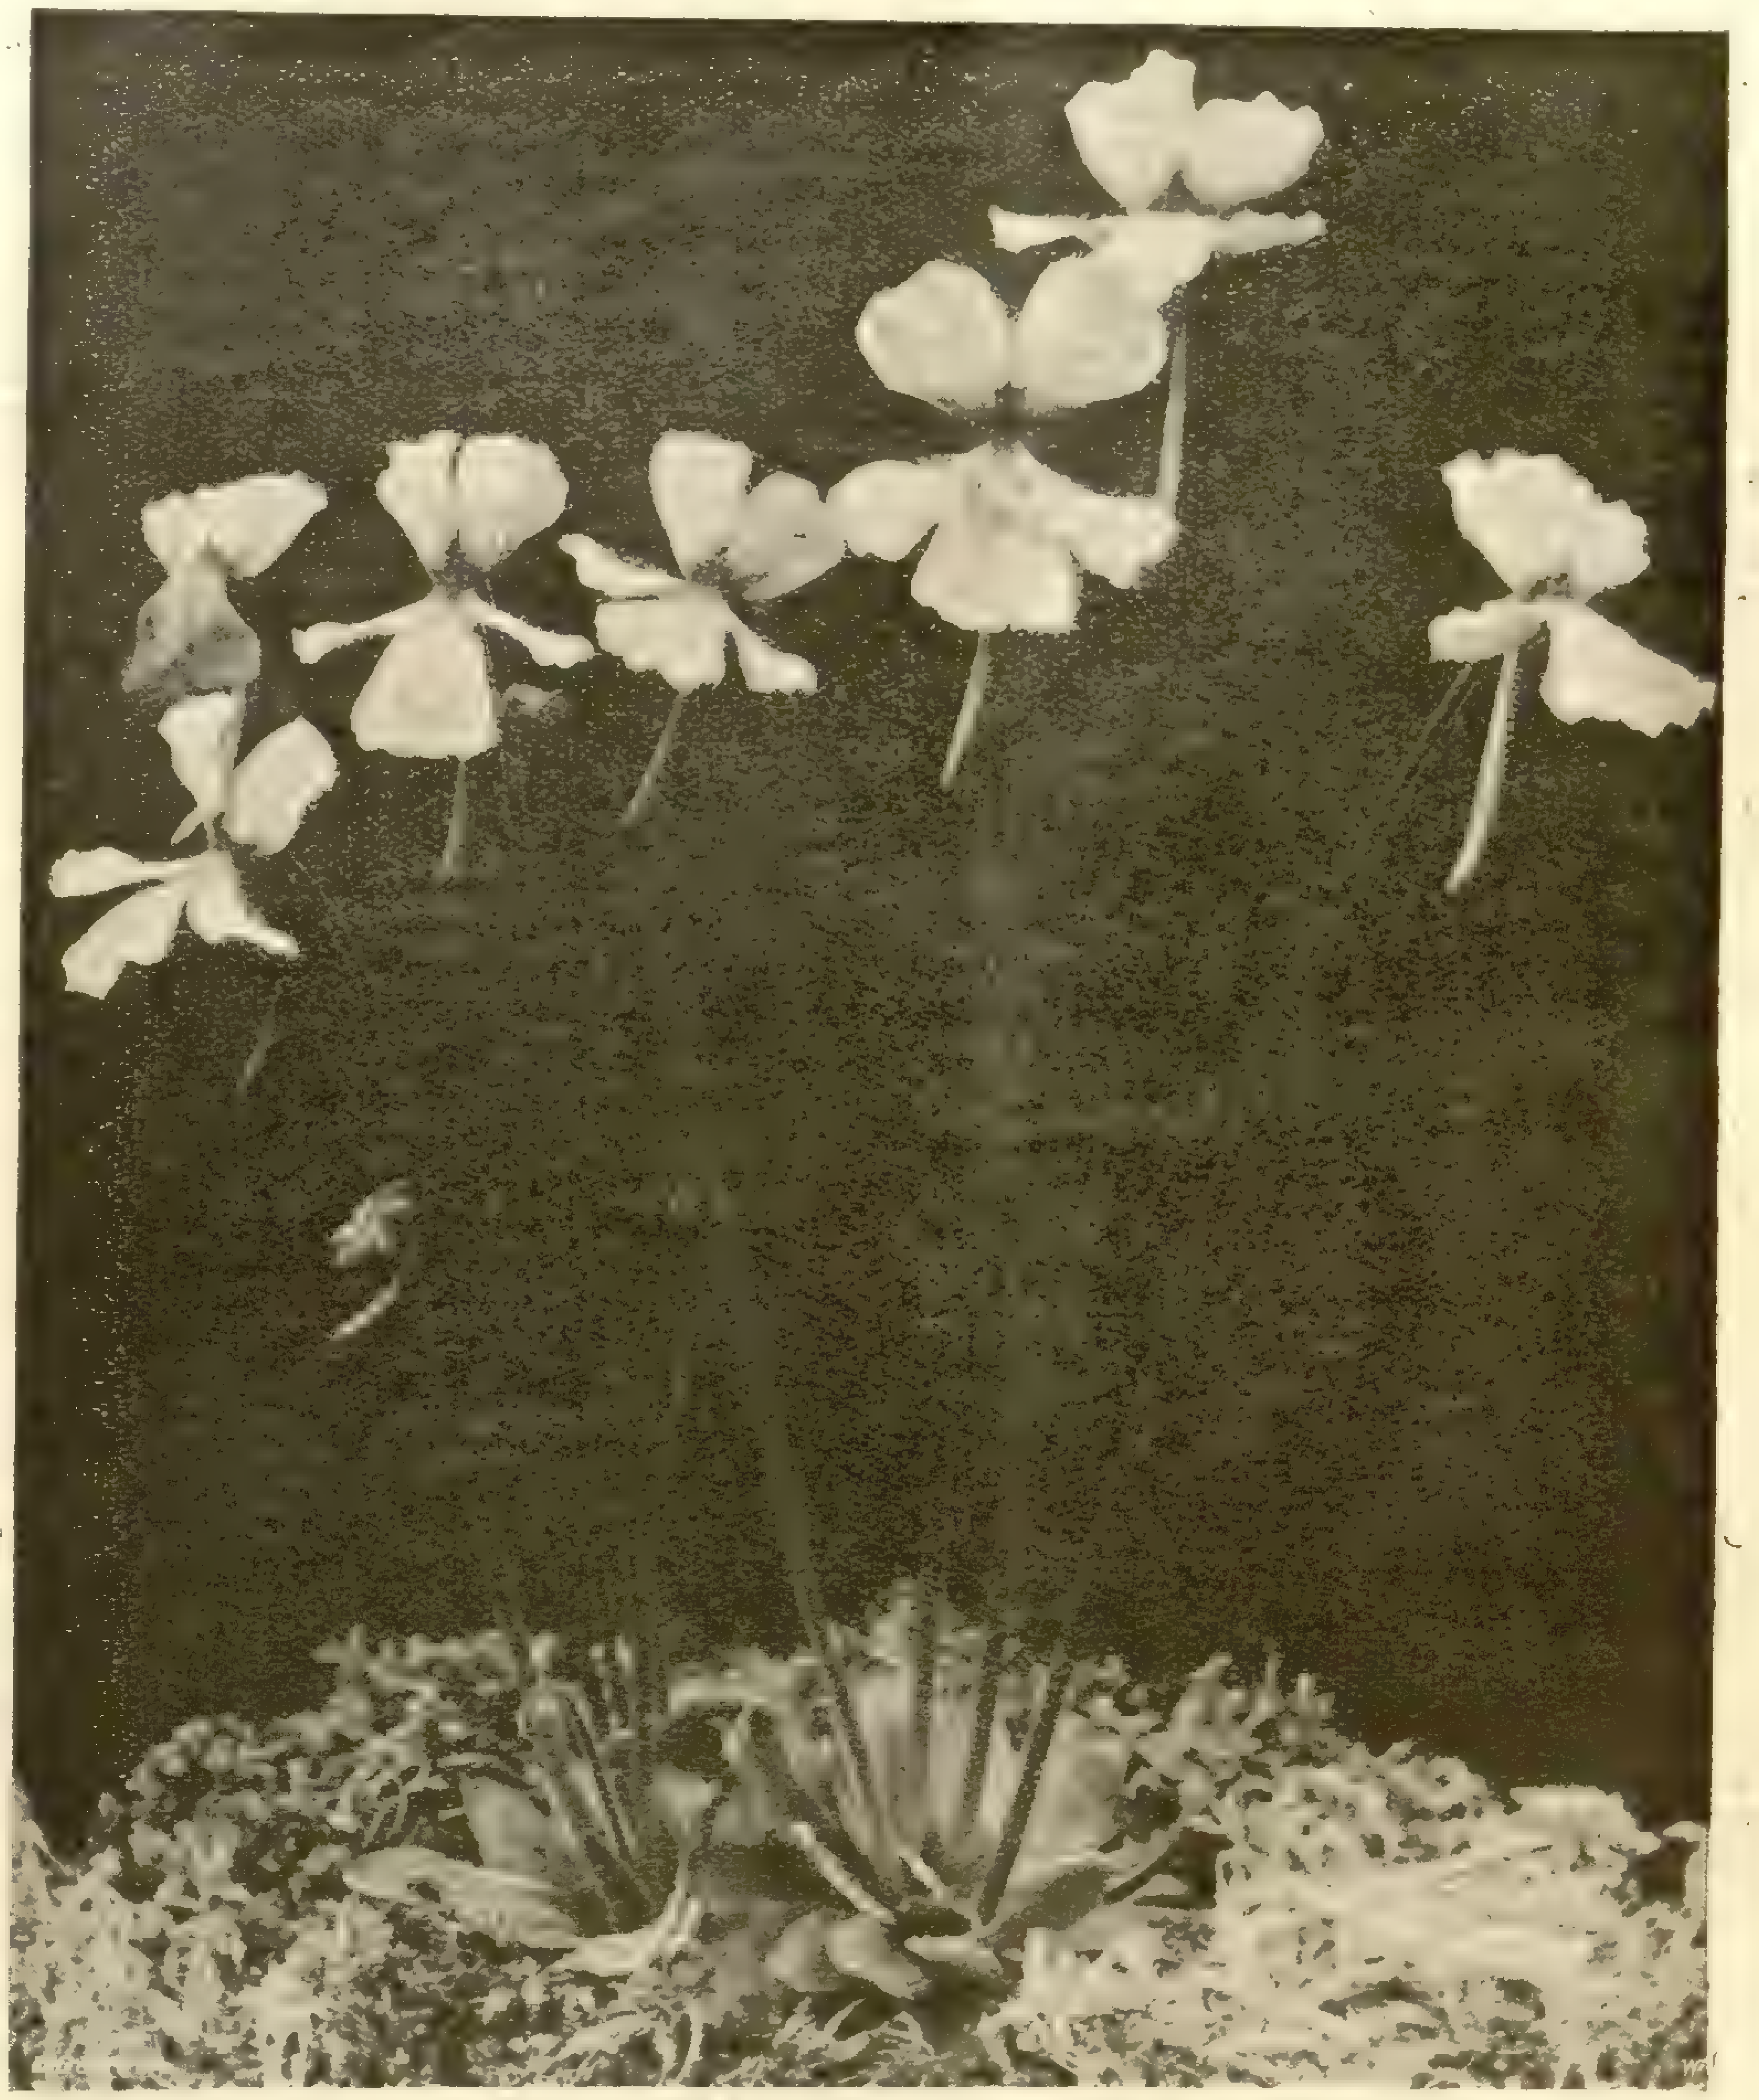

Fig. 12. Pinguicula Rosei: flowers violet-purple.

Publications Received.—*Transactions of the Scottish Horticultural Association.* Second series, Vol. III., Part 2. (Edinburgh: McFarlane & Erskine.) Price 2s. 6d. ***Fungi and Disease in Plants.*** By E. J. Butler. (Calcutta: Thacker, Spink & Co.) Price Rs. 15.

WINTER FLOWERS.

As might be expected from this side of England, Mr. Vicary Gibbs's list of "precocities" could be considerably extended here, and yet it would fall short of such a list compiled at the same date six years ago. Chimonanthus fragrans and Lonicera Standishii are now at their best. Garrya elliptica is laden with a great crop of graceful, silvery-grey catkins, some 8 inches long and still extending, a compensation for last year, when it gave no vestige of flower owing to the damage done in the previous hard winter.

Hamamelis mollis has been in flower for some weeks, and now H. japonica, with branches smothered by its gold-tipped, brown buds, and still carrying many of last year's nuts, is just opening.

Berberis nepalensis, with the native Daphne Laureola and Ruscus aculeatus, are all in flower.

Cornus Mas, Prunus Pissardii, and Rhododendron Nobleanum show coloured buds, but these, with many of the yellow Crocuses, now also showing colour, were flowering in the early days of January, 1913. Violets, Snowdrops, and Primroses are in sufficient numbers to provide a bunch of each.

Eranthis cilicica and E. hyemalis in quantity, with single specimens of Leucojum vernum, Scilla sibirica, and S. bifolia, Hyacinthus azureus, Anemone blanda, A. fulgens (in bud), and Iris reticulata var. Krelagei, are others of the brave little plants which scorn the suggestion that they are sure to suffer for it later. Erica hybrida, and even E. cinerea, with stray flowers of blue-eyed Mary (Omphalodes verna) peeping out from below, testify to an early season and a not unfavourable situation.

I have omitted several things that might be taken for granted to be in flower, such as Cydonias, in variety and quantity, and Iris unguicularis, which another correspondent from Aldenham alludes to as enjoying a hot summer for its rest, but actually it is for its season of growth that the summer heat is needed, though it also likes a sufficiency of thunderstorms, or their artificial substitute, and its short period of rest extends only from the end of its flowering season in March to May. Just before active growth commences in the latter month it can best be transplanted, though even then it resents disturbance. In its Algerian home it delights in the porous red soil of the coastal region.

With reference to the notes in your last issue on the Judas tree in London, the largest tree at Kew was 40 feet high in 1914, and so should now exceed in height (though probably not in girth) the specimen referred to by your correspondent. It may not be generally known that the flowers of Cercis Siliquastrum, and possibly of some of the other species, are edible, having a sweetish acid taste, and are, or may be, used as an ingredient in salads. *R. W. Rickards, Usk Priory, Monmouthshire, January 5, 1919.*

The following plants were in flower in the Happy Valley rock garden, Llandudno, on January 1, 1919: Aubrietia in plenty, Rock Roses, Erigeron mucronatus, Gentiana acaulis, Rosmarinus prostrata, Iberis sempervirens, I. saxatilis, Linaria hepaticaefolia, L. Cymbalaria, Violets, Campanula muralis, C. hirsuta, Saxifraga Burseriana Magna, Hippocrepis comosa, Coronilla glauca (in full flower), Linum flavum, Dianthus hybridus, vars. roseus and salmonea, Achillea rupestris, Tunica Saxifraga, Onosma tauricum, Armeria plantagineum, Arabis procurrens, Anchusa myosotidiflora, Cyclamen Coum, Megasea cordifolia, Myosotis, Pentstemons, and Roses. I have also recorded 83 varieties of wild flowers, found on the Great Orme, on the same date. *A. C. Axtell, Llandudno.*

ON INCREASED FOOD PRODUCTION.

POTATO MAJESTIC.

This variety was the first Potato I dug last year that pleased and surprised me by the size of the tuber and weight of crop. Many tubers were over 6 inches in length, though the soil was only 8 inches deep, with grass roots in the otherwise clean gravel beneath. We had no rain worth mentioning from April till July 9, notwithstanding several sharp thunderstorms. The tops of the Potatos of my neighbours went down flat in many cases long before the end of June, so that the conditions for success were far from being so good as mentioned on pp. 235 and 260, Vol. LXIV.; yet I estimated a yield of nearly 15 tons an acre. The seed I had was medium-sized for this large variety, and I cut all of the tubers, with a failure to grow of only 3.125 per cent. I have always been in the habit of cutting tubers that were too large for seed, and was not at all surprised that a few sets of Majestic failed to grow. Kidney or oblong Potatos always require careful cutting, so that only sets with eyes above the middle, at least, should be used. The basal end of this class of Potato is always weak and unreliable. I had more failures amongst other kidneys, although they came from Ireland, and were all of seed size. I attribute this to the fact that the vendors could not, or would not, let me have them early enough, with the result that the first and best sprouts were broken off, and a large proportion of the eyes looked decidedly doubtful at the time of planting. Owing to this delay, I could not begin planting till April 9, and Majestic was planted on the 24th, which I consider late for the South of England. This meant a bad start for the tubers, followed by a drought of ten weeks' duration, during the critical period of growth. I could not get 14 lbs. of seed size out of my crop, so Majestic is decidedly a big Potato. *J. F.*

Mr. Cuthbertson wonders if I have many seed-sized tubers in the crop of Majestic Potato. I can only repeat what I have already stated, which was that one quarter of the crop was of seed size, which is equal to 5 cwt. per ton.

The preparation of seed of this variety by cutting three days before planting is, in my opinion and experience, wrong. Cutting and planting should be done simultaneously, when the wound is sealed by the soil and air excluded. It is only the largest tubers that bleed after cutting, and by following my suggestion this loss can be reduced considerably.

Moss litter I find is a good manure for this vigorous Potato, but only a little should be used, because its vigour wants toning down instead of assisting, and as good tubers may be grown with but very little manure, it is best to err on the safe side by under rather than overmanuring.

I would suggest that a portion of the crop should be planted without manure with a view to obtaining tubers of seed size. Loss of vigour will naturally follow in time, particularly as it is a late sort, having a short season, and ripening prematurely. *John Robertson.*

USING UP WASTE.

I recently walked through country lanes, where I saw piles of road vergings and tons of scattered leaves lying by the roadsides, on the banks, here, there, and everywhere, and I could not help thinking what a waste it was that this material was not used for manuring the land at a time when ordinary stable or farmyard manure is at such famine prices and almost impossible to obtain.

How to use this valuable material is not a difficult problem to solve. One way of utilising a large quantity of it would be to dig it into the subsoil to improve the depth of good ground.

A much more useful manure is formed if this waste material is mixed with such powerful material as the waste from earth closets, or, if that is unobtainable, with slops rich in urine from the house. I believe in using as much urine as can be conveniently obtained, since it will quickly turn a poor but humic manure into one very rich in plant-food. There are difficulties, of course, but these are not insurmountable.

From a practical standpoint, the leaves and sidings should be well saturated with the urine or mixed with one-fourth their own bulk of the closet refuse, and either dug in immediately or allowed to mellow for a month or so, and dug in during early March (for light soils). A little crushed gypsum will serve to fix the ammonia, and a covering of earth over the heaps will render them inoffensive. *E. T. Ellis.*

PEAS AND BEANS.

As the cropping and quality of the "Pois mangetout Breton" seemed good in the form of the ripened Pea, I put in three rows of nine yards. Owing to the drought, a few plants "miffed" off in their seeding, and the others were not quite so full of pods as was usual However, the dried crop was $11\frac{3}{4}$ lbs., which seems fairly heavy. The plants were supported by three-feet-wide wire netting, and covered in with string netting before birds had done very much damage. Of climbing Beans, only Dai Fuku was weighed; from those grown to full height the yield was $3\frac{1}{4}$ oz. per plant. Of the dwarfs (mentioned in *Gard. Chron.*, July 27, 1918, p. 31), all the sorts gave from 50 to 55 pods per plant where in rows not too crowded or overshadowed, but the little Prédome on good plants carried 70 to 75 pods, 77 being the maximum noted; possibly, with special "show table culture," it would rise even higher; ten plants taken from the rows showed an average of 1.6 oz. per plant. The red and green flageolets gave 1.2 to 1.6 oz. Grown between rows of Potatos ($4\frac{1}{2}$ feet space), the Brown Dutch only yielded 0.45 oz., whilst in the same row the "café au lait" Bean gave just on 1 oz.; this is, no doubt, due to the early nature of the latter, which had time to grow freely before the Potato haulm had become too high.

Of the Japanese dwarfs, Paga Udzara gave scanty pods, and seemed of little worth in the flageolet group; Kintoki, though only giving about a score of pods on a patch where other sorts were giving 50, is, perhaps, worthy of another trial, as the seeds are large and plump, and the pods seemed somewhat free of membrane; moreover, the flavour has yet to be studied.

Are we going to mend our ways on the show table? Is there any use in exhibiting plates full of Bean pods? So far as concerns dwarf varieties, one whole plant should be staged to show its productiveness and habit; with climbing varieties a fair section of the plant could be cut and staged, and thus show whether the pods were well distributed and in uniform bunches or pairs; mere size of individual pods selected become only of value when they are of a degree of advancement in maturity which will show whether the variety is a good "mange tout" type, or is to be classed as a membrane-forming flageolet type. Whilst in a real mangetout the seeds may attain very nearly their full size with the pods still succulent, the flageolet types should be judged where they are intended to serve the two purposes, by the degree of development of the seed, accompanied by freedom from membrane, otherwise by the size and quality of the seeds. We should get some semblance of law and order by making distinct classes or groupings. First, by habit into the Climbing and Dwarf sorts, and then sub-dividing each of these into mangetouts and flageolets.

CLIMBING.—(1) Multiflorus group—the scarlet and white Runners (by some French seedsmen these are included amongst the flageolets). (2) Mangetout—membrane-free but with strings. (3) Mangetout—membrane-free but without strings. (4) Waxpods—free from membrane, with or without strings. (5) Flageolets—in which the pods develop membrane more or less early.

DWARF.—(1) Mangetout—with strings. (2) Mangetout—without strings. (3) Waxpods. (4) Flageolets.

From the standpoint of food values the more valuable sorts would be those in which the greatest development of seeds was permissible. From the standpoint of flavour, which is to some extent dependent upon the actual cooking, we come more or less to the deadlock of "chacun à son goût." The very characteristic flavour of the multiflorus group would make a membraneless race very agreeable, and is perhaps possible by selection.

Some varieties seem much more stable than others; for instance, the dwarf Prédome rarely seems to sprout, quite occasionally one has a climbing item arising, and sometimes a plant yields flattish pods, which are correlated with some membrane development, and a longer shaped seed than that of the type, which is almost Pea-like in habit, a correlation of interest to those that have not the advantage of home-saved seeds. *H. E. Durham.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Birds and Fruit Buds.—The able gardener at Gunnersbury House appears to be not afraid of sparrows, nor has he any special desire to get rid of these birds, but I would gladly go to considerable lengths to keep the garden clear of them all the year round. Sparrows destroy fruit buds and spoil many of our garden crops, and if by accident they miss any fruit buds of Currants, Gooseberries, and Plums, they pick the blooms to pieces when the buds expand. As the Plum trees are of large size, it is impossible to cotton them over, as Mr. Hudson has suggested. Sparrows are so destructive here that the cultivation of Sweet Peas, culinary Peas and Lettuces, has had to be abandoned. The garden here is a large one for the neighbourhood, and is surrounded by small gardens and houses, consequently I am afraid to use a gun. When living in Richmond Park, with a large garden to look after, I noticed that many more species of birds came for food than is the case at Brixton, and sparrows were few in number. Perchance the thrushes, blackbirds and finches kept the sparrows away; if this is so, I wish they would come to reside here, as I can deal with them better than with the sparrows. *William Chaffer, Broadlands, Effra Road, Brixton, S.W.*

Silver Leaf Disease.—During the past six years, whilst engaged in practical horticulture, I had many opportunities for observing the disastrous effects produced by Silver Leaf disease, and some months ago I commenced a research with the object of finding out: 1st, whether "Stereum purpureum" is responsible for all cases of Silver Leaf; and 2nd, to discover means of prevention and remedy of the disease. The material used for these investigations was invariably taken from naturally "silvered" plants growing in the field, and not from inoculated plants or from those which had already been killed as the result of Silver Leaf. The presence of hyphae (spawn) in the tissue, roots, stem, branches, twigs, and suckers of "silvered" plants, so far examined, indicates that a fungus is the main cause of this disease. The hyphae in their tissues are identical with those produced by Stereum purpureum. Where the trouble comes from the soil, as stated by Mr. Molyneux, it certainly originates from the superficial roots, which have become injured by various agencies, plough, spade, etc., thus providing a ready entrance for the fungus Stereum purpureum, which is, according to my observations and others, an obligate parasite. The results of these investigations, dealing with the first question, will be published very shortly, and I trust that they will convince horticulturists of the cause of the disease. The primary preventive measures to be adopted are: 1. The extermination of the fungus Stereum purpureum wherever found, parasitically or saprophytically. 2. When amputating a branch or side branch with a saw, it is essential that these branches should be cut off as near as possible to their main axis or to their point of origin, in order to encourage more rapid callusing. A clean cut with a knife should always follow the saw, and wherever a round or jagged surface is noticed. Whenever pruning a branch the cut surface should be tarred immediately and not a week or a month after the operation. The spores of the fungus which are blown about by the wind alight on an open wound, germinate readily, and the penetration into the tissue begins. 3. In plantations where the plough is used for the cultivation of catch-crops, it is difficult to prevent injury to superficial roots, but injury may be minimised by a more careful use of the spade, and by pulling up suckers. Varieties of Plums grown on their own roots produce only a few or scarcely any suckers, and hence their planting should be encouraged wherever possible. 4. Deficiency of lime in the soil and unsatisfactory drainage, together with an excess of the other soil constituents, weaken the constitution of Plums and other trees and shrubs, and render them more susceptible to disease. Occasionally trees grown under such abnormal conditions, especially if attacked by red spider or insect pests, or if top-grafted on an unsuitable stock, may appear to the naked eye to be silvered, but in reality this is not "True Silver Leaf" but "False Silver Leaf," the cause of which is to be attributed to physiological weakness. Root-pruning of such false silvered trees or shrubs, and improved cultural methods, may lead to recovery in the following season. 5. Planting of resistant or less susceptible varieties like the Yellow Pershore Plum or Early Rivers. The former roots readily from ripe cuttings, and also possesses qualities as a stock for grafting or budding. Other remedial measures are described in the Food Production Leaflet No. 58, and I endorse the views expressed therein, and those of Mr. Brooks, *Gardeners' Chronicle*, Dec. 28, 1918. The testing of immune varieties of Apples and Plums, as well as their stocks used for grafting, is in progress, and other control measures are to be carried out during the coming season at the R.H.S. Gardens, Wisley. Growers should be in a position to distinguish between "False" and True Silver Leaf before completely condemning their plants. Practical experience makes me realise the extra labour involved in tarring the cut surfaces when pruning stone fruits. It is quite evident that those stone fruit trees and other shrubs annually subjected to pruning, fall victims much sooner to Silver Leaf than those on which this practice is not followed. *Jean Bintner, Imperial College of Science, South Kensington.*

—— It seems to be generally agreed that Silver Leaf disease is due to infection; it is also very commonly advised to cut away diseased branches. But does one see anywhere any recommendation to cleanse or disinfect the saw or sécateurs before proceeding to another cut after having lopped off a piece perhaps in a diseased region? It is, perhaps, not a matter of doubt that anyone would have a chance of being operated upon twice by a surgeon who first cut into the borders of an abscess and then proceed to open the abdomen with the same knife uncleansed between whiles. I fancy that all tools being used should be in duplicate, and while one was being used the others should be soaking in some efficient antiseptic. Any antiseptic requires a certain amount of time to act efficiently. Then there is the question of cleansing the wound, dressing and sealing it. Mr. Brook's contention (however well founded) recalls the case of those who claimed to have cured cases of "pernicious anaemia," for they were gainsaid by those who held that if cure ensued, the disorder could not have been the real disease. Be that as it may, heavy infection with mealy aphis will cause a somewhat Silver Leaf-like appearance on a Plum tree; and one of my trees of the Victoria variety was thus diagnosed and condemned by a visitor. This aphis was especially abundant in the past summer, and one Gage tree was simply swarming with the insects all over its stem and branches, as well as its leaves: on the stem they were well exposed to a remedial spraying. *H. E. D.*

Mangold Wurzel (p. 254, Vol. LXIV.).—Surely the proper spelling is simply that used by the German, viz., Mangel Wurzel ("want" or "need," and "root"), i.e., the root for time of need. The other spelling, if correct, whence does it come? I have no Danish or Swedish dictionary, but these would appear to be the only other intermediaries. In French the plant is called Beet (Betterave or Bette), and if the German term is to be avoided otherwise than by a mangled spelling, the term "Field Beet" might be used. But it would take many centuries to induce the farmer to adopt a new term. *D.*

Austrian Hybrid Roses (see p. 10).—I agree with Mr. Walter Easlea that the title "Austrian Hybrid Roses" is wrong, but further than this I differ from him very materially. The name "Rosa Pernetiana," apart altogether from any other consideration, is a botanical error, and I am surprised that an authoritative body, such as the National Rose Society, should allow such a designation to stand. The title which Mr. Easlea so strongly advocates is one that could only be given to a new species. M. Pernet Ducher's introductions are only Hybrid Roses. Pernet Roses should, therefore, be quite in order. When I was a member of the Council of the National Rose Society, and the name of R. Pernetiana was proposed, I opposed its adoption, and was successful. When I had ceased to have an official connection with the Society the name was subsequently proposed again, and was sanctioned. If this practice, however, of naming Roses is begun it is difficult to know where it will end. So far as "Austrian Hybrid Roses" are concerned, I believe that the name of "Persian Roses" would be a more accurate one for them. When all is said, however, it really matters little what name is chosen, because so long as the present obsolete method of classification stands as it does, the "Austrian Hybrid Roses" are simply merged in that awful jumble known as the Hybrid Teas. Whilst granting the good work in the hybridisation of Roses that has been done by M. Pernet Ducher, it is but right to say that the eminent French raiser does not stand alone. Quite as valuable and outstanding work has been done coeval with, if not prior to, his by at least one British raiser. The study of the evolution of the Rose has demonstrated—to me at least—that Persian "blood" was first used by an Irish firm. Care should be taken, however, in putting hybrids of such into commerce, and for a reason now well known to rosarians. Black Spot was a very decided accompaniment of certain Persian Hybrid Roses. Let Mr. Easlea read the ninth and tenth Masters' Memorial Lectures by Professor R. H. Biffen, M.A. (see *R.H.S. Journal*, Vol. XXXIX., pt. 2), and Lord Penzance's able article in the *Rosarian's Year Book* for 1896. The experiences stated therein have been confirmed by many Rose growers. In yellow Roses, Mrs. Wemyss Quinn is as superior to Rayon d'Or as day is to night. Would Mr. Easlea call Mrs. Wemyss Quinn a "Pernetiana" Rose? *George M. Taylor, Mid-Lothian.*

Senecio saxifragoides and S. lagopus (see p. 18).—There seems to be pretty close analogy between the behaviour of these two forms of Senecio and that of our British Polygonum amphibium, which, when growing in the water, is quite glabrous, but when growing, as it does with equal freedom, on dry land, has downy leaves. It is said, though I have not proved it by experiment, that "one form changes into the other if the plant is moved from dry land into water or vice versa." (Avebury's *British Flowering Plants*, p. 348). *Herbert Maxwell, Monreith.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 13.—At the meeting held at the London Scottish Drill Hall, on the above date, there was a fair attendance of Fellows and visitors, and a most interesting exhibition. Orchids provided the predominant feature, and the several excellent groups of these flowers were very greatly admired. In the group awarded a Gold Medal there was a goodly batch of the charming Calanthe Harrissii, carrying numerous elegant spikes of white flowers. Vegetables, hardy plants and Ferns were the other leading features.

The Fruit and Vegetable Committee awarded two Medals; the Floral Committee granted one First-class Certificate and five Medals; and the Orchid Committee recommended one Award of Merit and two Preliminary Commendations to novelties, and awarded five Medals to groups.

Floral Committee.

Present: Messrs. H. B. May (in the chair), John Green, G. Reuthe, C. R. Fielder, J. F. McLeod, W. Cuthbertson, W. Howe, A. Turner, J. Jennings, Thos. Stevenson, H. J. Jones, J. W. Moorman, C. Dixon, J. Dickson, Chas. E. Shea, E. F. Hazelton, Jas. Hudson, E. H. Jenkins, W. B. Cranfield, R. C. Notcutt, Sydney Morris, R. W. Wallace, J. W. Blakey, J. W. Barr, Chas. E. Pearson, and W. J. Bean.

FIRST-CLASS CERTIFICATE.

Cotoneaster glaucophylla.—We do not know the authority for the above name, but, judging from the specimens exhibited, there was not much evidence of glaucous colouring in the neat leafage. Cotoneaster glaucophylla fruits very freely, and carries its small reddish berries in loose panicled clusters along a great length of its graceful branches. At Wisley the plant grows about 5 feet high, and a group of about a dozen specimens near the Iris collection is very effective throughout the winter. It is a free-growing shrub, but under the poor light at Westminster its fruits appeared to be very dull in colour; we understand, however, that in the clearer atmosphere and better light of the country the plants are very bright while in fruit. Shown by the ROYAL HORTICULTURAL SOCIETY from the Wisley Gardens.

GROUPS.

Juniperus pachyphlaea elegantissima, elegant in form and bright glaucous-green in colour, was effective in a group of hardy plants submitted by Messrs. PIPERS (Silver Banksian Medal). A beautifully flowered plant of Rhododendron mucronulatum, covered with bright rose-purple blooms, was conspicuous in Mr. REUTHE's contribution of hardy plants (Bronze Banksian Medal), while forced Daffodils and Primroses brightened the display made by Mr. G. W. MILLER (Silver Banksian Medal).

Perpetual-flowering Carnations added their charm of fragrance, colour, and form to the meeting. Messrs. STUART LOW AND CO. showed Red Ensign, Eileen (salmon pink), and Brilliant in good form (Silver Banksian Medal). Sprays of Pyracantha Gibbsii (see *Gard. Chron.*, February 2, 1918, fig. 21) were shown from the R.H.S. Garden, Wisley, as evidence of the brilliance of the fruits and the length of time these remain on the shrub untouched by birds.

A batch of the old Single Lilac Primrose full of blooms was very bright in a small group of Alpine plants and shrubs from Messrs. J. CHEAL AND SONS. Messrs. H. B. MAY AND SONS showed Ferns and Cyclamens (Silver Flora Medal).

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Jas O'Brien (hon. secretary), W. Bolton, Walter Cobb, R. A. Rolfe, C. H. Curtis, C. J. Lucas, W. H. White, J. Cypher, J. E. Shill, J. Charlesworth, W. H. Hatcher, Fred. K. Sander, T. Armstrong, A. McBean, E. R. Ashton, Pantia Ralli, F. J. Hanbury, R. Brooman White, R. G. Thwaites, J. Wilson Potter, Stuart Low, and Arthur Dye.

AWARD OF MERIT.

Cypripedium Perseus (Lady Dillon × Alcibiades illustris), from W. R. LEE, Esq., Plumpton Hall, Heywood, Lancashire (gr. Mr. Branch). One of the finest and most perfectly shaped of its class. The dorsal sepal is white with closely-arranged spotted lines of dark claret colour shading to a lighter tint towards the edge. The petals are dark brownish-rose with purple line up the centre; the lip is brownish-rose with yellow margin. Staminode yellow.

PRELIMINARY COMMENDATIONS.

Odontoglossum Princess Patricia (Dora × crispum Luciani), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells. A charming seedling, with flower of great size and rich colour. The inner two-thirds of the segments are blotched with Indian-red on a white ground. The lip is white with a large claret-red blotch in front of the yellow crest.

Odontoglossum Triumph (ardentissimum × Ossulstonii), from Messrs. ARMSTRONG AND BROWN. A fine seedling, of perfect shape, the inner two-thirds of the segments being claret-red, the outer-third blush-white with purple tinge from the back of the flower.

GROUPS.

Messrs. CHARLESWORTH AND CO. were awarded a Gold Medal for a group, the centre of which was composed of white Calanthe Harrissii, and the sides of good Odontoglossums, Odontiodas, and Miltonias. Amongst new and rare plants we noticed as being specially good Odontoglossum Tityus (crispo-Harryanum × President Poincaré) and O. Gorizia var. purpureum, both of violet-purple colour; Odontioda Marjorie var. grandis (Oda. Joan × Odm. Alexandrae), Oda. Lyra (Odm. Jasper × Oda. Royal Gem), and Oda. Dulcies (Oda. Cooksoniae × Odm. illustrissimum), all grand varieties.

Messrs. ARMSTRONG AND BROWN were awarded a Silver-gilt Flora Medal for a fine group, in which were various hybrid Cymbidiums, arranged with brightly-coloured Odontoglossums, Odontiodas, Cattleyas, and Laelio-Cattleyas. The handsome Odontioda Madeline var Princess Patricia, yellow blotched with red, and the darkly blotched Odontoglossum Aglaon auriferum, the first of the cross to have a yellow ground, were specially attractive.

Messrs. J. AND A. MCBEAN, Cooksbridge, were awarded a Silver Flora Medal for a group in which their famous hybrid Cymbidiums were a prominent feature; they included C. Schlegelii giganteum, one of the largest and best of the class; varieties of C. Alexanderi, C. sandhurstense, and hybrids of C. erythrostylum, Odontoglossum Princess Mary, from the Brackenhurst collection, was shown exceptionally finely in this group.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for an effective group, including the stately Brasso-Cattleya Penelope, with a four-flowered inflorescence, various showy Laelio-Cattleyas, Sophro-Cattleya Doris in three forms with varying tints of scarlet, and Sophro-Laelia Leda.

Messrs. J. CYPHER AND SONS, Queen's Road Nurseries, Cheltenham, were awarded a Silver Banksian Medal for a group of finely-grown Cypripediums, including C. Draco, of very dark colour; C. Stanley Maude, a finely shaped flower with pure white upper half to the dorsal sepal; C. Minos Youngii, C. Victor Hugo, C. Queen of the Belgians, and the delicately tinted C. insigne Snow Queen, with a snow-white dorsal sepal. A fine specimen of the rare Masdevallia Gargantua and M. tovarensis, with five flowers on a spike, were also included in the collection.

Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill), sent cut spikes of the beautiful Brasso-Cattleya Cliftonii albens, acquired from the Brackenhurst collection, with large, clear white flowers, and Laelio-Cattleya Schröderae (Bella alba × C. Maggi Raphael alba).

G. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. Redden), showed Odontioda The Sphinx (parentage unrecorded), a beautiful dark violet flower with a bronze-red shade.

E. R. ASHTON, Esq., Broadlands, Camden Park, Tunbridge Wells, showed Sophro-Laelio-Cattleya Isabella (C. Fabia × S.-L.-C. Marathon), a showy rose-tinted flower with Tyrian-purple front to the lip.

Sir JEREMIAH COLMAN, Bart., showed a good specimen of the pure white Coelogyne Mooreana, cut flowers of Laelio-Cattleya Brian (Goodyi × Colmaniana), and Calanthe Gatton Alpha, a good white variety with pink lip.

Messrs. SANDERS, St. Albans, staged Cymbidium Atalanta (Lowianum × insigne).

Messrs. FLORY AND BLACK, Slough, showed a selection of good hybrid Odontoglossums. Also Sophro-Laelio-Cattleya Ruth, of bright red colour on a yellow ground.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), J. Cheal, Owen Thomas, G. Bullock, Ed. Harriss, P. D. Tucker, A. Bullock, A. R. Allan, A. W. Metcalfe, F. Jordan, E. A. Bunyard, W. H. Divers, G. P. Berry, J. W. Bates, W. Poupart, and Rev. W. Wilks.

Some excellent Leeks, great in girth if not extraordinary in their blanched length, were exhibited by Mr. R. STAWARD, Panshanger Gardens, Hertford; the varieties represented were Monstrous Caranten, Ayton Castle Giant, Sutton's Royal Favourite, The Lyon, Monarch, Prizetaker, and Improved Musselburgh. Monarch and Royal Favourite appeared to have greater girth than the other varieties, and reminded us of the "pot Leeks" so largely grown and shown by the Northumbrian miners (*Silver Knightian Medal.*)

An attractive and interesting display of hardy winter vegetables, arranged by Messrs. SUTTON AND SONS, included five varieties of Onions, two of Celery, Prizetaker Leeks, Christmas White and Super Early White Broccoli, New Year Savoy, Celeriac, Couve Tronchuda, Red Globe and Early Snowball Turnips, Christmas Drumhead Cabbage, Tender and True Parsnip, two varieties of Carrots, two of Brussels Sprouts, two of Beet, and three of Kale. (*Silver-gilt Banksian Medal.*)

The brilliantly coloured Crawley Beauty Apple, a fine keeper and of fair quality, was splendidly shown by Messrs. J. CHEAL AND SONS.

NATIONAL DAHLIA.

MR. JOSEPH CHEAL presided at the Annual General Meeting of this Society, held at 35, Wellington Street, W.C., on Monday, January 13. There was a moderate attendance, consisting entirely of officers and committee.

REPORT OF THE COMMITTEE FOR 1918.

The Committee again have the pleasure of recording a very satisfactory year's work, although the abnormal conditions due to the continuance of the war still remained through the season. The season was adverse to the growth and to the flowering of Dahlias. The membership of the Society remains satisfactory under present conditions.

The Floral Committee, acting in conjunction with the Floral Committee of the R.H.S., held four meetings during 1918. The number of seedling Dahlias submitted for award was 168, and no fewer than 43 gained the First-class Certificate of the N.D.S., and the Award of Merit of the R.H.S. These awards were made to all sections of the flower, and the fact that so many excellent new varieties were forthcoming during a period of war shows that valuable work in the progress of the Dahlia is still maintained, and points to an era of prosperity for the Dahlia in the near future. In this connection it is of interest to record the fact that in 1917 121 seedlings were submitted, and 55 Certificates were granted.

The Annual Floral Meeting was held at the London Scottish Drill Hall, Buckingham Gate, by the kindness of the Council of the Royal Horticultural Society on September 10, and the Committee again record their gratitude to the Council of the R.H.S. The exhibition was very satisfactory under the circumstances, the entries being more numerous than at the previous show. Amateurs were well represented, while the quality of the flowers was fully up to the usual standard.

The competition for the valuable Cory Cup was held on the same day. The difficulties of labour and transport under war conditions prevented the number of competitors from being as numerous as they would otherwise have been.

The Committee deemed it advisable to still discontinue the conferences and publication of the *Year Book* for the present. The new varieties and selection of the best sorts were, how-

ever, compiled and published in the Supplement and schedule to keep up a continuous record. The Committee hope, however, to resume their activities in this direction shortly. They still continue to give their attention to all sections of the flower, believing this to be the true policy.

The Report was presented, and a balance of about £20 10s. 5d. was reported; the report and financial statement were adopted on the motion of the Chairman, who considered the Society's affairs satisfactory, in spite of war conditions.

Mr. Reginald Cory was re-elected President; Mr. J. Green, Treasurer; Mr. J. Cheal, Chairman; and Mr. J. B. Riding, Secretary. All were heartily thanked for past services, and Mr. Riding was granted an honorarium of £10. The Committee was re-elected, with the addition of Mr. A. C. Bartlett, to fill a vacancy, and Mr. Mortimer was made a Vice-President. Executive, Classification, Finance, and Floral Committees were elected without alteration; the latter consists of Messrs. Jarratt, Crane, Cheal, Curtis, and Riding. Mr. D. B. Crane was appointed auditor for 1919, and Mr. G. Davidson thanked for his past services in this office.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 19.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, A. G. Ellwood, J. Howes, J. Lupton, D. McLeod, J. McNab, E. Rogers, W. Shackleton, J. Thrower, and H. Arthur (Secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cypripedium Perseus var. alpha (Lady Dillon × Alcibiades illustris) (a Silver Medal was also awarded); *Cypripedium Elise* (Lady Dillon × Hermes); and *Odontoglossum crispum var. Thelma*, all from W. R. LEE, Esq.

Cypripedium Armistice (Antinous × nitens), and *Vanda Wrigleyi*, from Mrs. BRUCE and Miss WRIGLEY.

Laelio-Cattleya Gen. Maude var. Victory (L.-C. rubens Lambeauianum × C. Hardyana), and *Cypripedium Princess Patricia var. magnificum* (C. nitens G. S. Ball's var. × Alcibiades illustris), both from P. SMITH, Esq.

Odontioda Ashworthiae (Vuylstekeii × Thwaitesiae), from R. ASHWORTH, Esq.

Cypripedium Eileen Hanmer (aureum Surprise × Bianca), from A. HANMER, Esq.

Brasso-Cattleya Pallas var. Surprise (B.-C. Digbyana Mossiae × C. gigas), from Messrs. CHARLESWORTH AND Co.

Laelio-Cattleya Queen Empress (C. Mossiae × S. grandiflora), from Messrs. S. LOW AND Co.

AWARDS OF MERIT.

Cypripedium Idox var. Easter (Beryl × Ossulstonii), from the Rev. J. CROMBLEHOLME.

C. aureum Excelsior, from S. GRATRIX, Esq.

C. Golden Dawn var. chesterense (Golden Gem × Sanacderae), from S. HANMER, Esq.

Laelio-Cattleya Linda var. Orange King (L.-C. Arachne × C. aurea), from Messrs. STUART LOW AND Co.

CULTURAL CERTIFICATES.

To Mr. E. ROGERS, for *Laelia Gouldiana* and *Platyclinis uncata*.

To Mr. J. LUPTON, for *Cypripedium Leeanum giganteum*.

GROUPS.

S. GRATRIX Esq., Whalley Range (gr. Mr. Howes), was awarded a Large Silver-gilt Medal for a group composed principally of choice Cypripediums; Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. E. Rogers), were awarded a Silver-gilt Medal for a collection; W. R. LEE, Esq., Heywood (gr. Mr. C. Branch), and Col. Sir J. RUTHERFORD, Bart., Blackburn (gr. Mr. J. Lupton), were awarded Silver Medals for collections.

SOUTHAMPTON ROYAL HORTICULTURAL.

JANUARY 6.—The annual general meeting of the above society was held at the local Municipal Offices on the 6th inst. The President, the Right Hon. Lord Swaythling, presided, and he was supported by the Mayor of Southampton and the Rev. Professor Lyttel, Chairman of the Borough Council.

There was a good attendance of the members. The meeting was first made special to alter the rules, for the purpose of empowering the Council to elect a new secretary. The rule having been passed, the annual report and statement of accounts were submitted. The report called attention to the splendid financial success of the Rose Show, but regretted the small attendance at the Summer and Autumn Shows, especially at the latter, which was honoured by the visit of an influential deputation from the Council of the Royal Horticultural Society.

Notwithstanding the disappointments alluded to, the accounts showed a net credit balance of over £33 on the year's working, the cash assets amounting to £164 8s. 3d., against £131 7s. 2d. at the end of 1917. The account also included an item of £176, divided between the funds of the British Red Cross and the Order of St. John.

Lord Swaythling was re-elected President, and the other officers were re-elected, with the exception of the Secretary, Mr. C. S. Fuidge, who did not seek re-election. On the proposition of the Chairman, Mr. Fuidge was elected a life member of the Council and hon. consulting secretary. The Council had previously provisionally elected Mr. M. W. Beer as Secretary. Lady Swaythling presented to the successful competitors the R.H.S. Medals, 24 in number, awarded at the Autumn Show.

MR. ANDREW IRELAND, OF MESSRS. IRELAND AND HITCHCOCK.

The President, speaking in very eulogistic terms of Mr. Fuidge's services, said that to have retained his connection with the society for half a century he must have shown great tact, tenacity, and organising ability, with a very large share of the blessing of good health. It therefore gave him the greatest pleasure, on behalf of a large number of subscribers, to ask Mr. Fuidge to accept a cheque for £100 as a mark of their esteem.

Mr. Fuidge, in returning thanks, gave some reminiscences of his early connection with the society, stating that previous to his joining the Committee in 1868 he was an amateur exhibitor at the society's shows, and was an allotment holder as far back as 1862. After alluding to his collaboration with the founder of the society, Lieut.-General Lacey, he sketched the progress of the society to the present time, showing that it owed its present existence, and the favourable balance-sheet, to the late Lord Swaythling, and since to Ellen Lady Swaythling. Being within a few months of his 80th birthday, and although enjoying good health, he considered it time he gave place to a younger man, but he hoped still to be of use to the society.

TRADE NOTES.

MR. ANDREW IRELAND.

So well known is Mr. Andrew Ireland to all who frequent the London and principal provincial flower shows, that he was sure of a hearty welcome into the arena of commercial horticulture, when, last autumn, he set up business on his own account at Mark's Tey, after a long period of service as a grower and exhibitor for Messrs. Dobbie and Co. As a raiser and cultivator of both vegetables and flowers, Mr. Ireland is a prominent figure in British horticulture to-day, and few men can more quickly and accurately sum up the merits or demerits of a plant or flower than he can. No desirable tone of colour, improvement in form or texture escapes his notice in any new variety, whilst his power of selection amounts to genius. Added to this, his great natural ability and sound reasoning enable him to understand his subject and induce it by proper treatment to yield its best. His criticisms are always eagerly listened to and respected, and those who most quickly wend their way to any exhibit he has put up are the men most interested in the subject on view. When new varieties of plants, flowers or vegetables are exhibited, the keenest competitors are ever anxious for his opinion and criticism.

Mr. Ireland is an acknowledged authority on Sweet Peas, with which in the mind of the general public he is more identified than with most other plants. Certainly all lovers of Sweet Peas owe him a debt of gratitude for his untiring efforts and success in establishing true stocks of Spencer Sweet Peas, and also for the many grand varieties he has helped to produce. At all the important exhibitions throughout the country splendid exhibits of Sweet Peas, Antirrhinums, Tulips, Aquilegias, Scabious, and other flowers, grown and staged for his late employers, Messrs. Dobbie and Co., have won high honours and proved Mr. Ireland's capabilities as cultivator and showman. Readers will join with us in wishing success to the new firm of Messrs. Andrew Ireland and Hitchcock, Mark's Tey, Essex.

MR. E. SCAPLEHORN, for many years manager of the hardy plant department in Messrs. W. Cutbush and Son's Highgate Nurseries, and latterly in a similar capacity with Messrs. James Box and Co., Lindfield, is commencing business on his own account as a hardy plant specialist, at Lindfield, Haywards Heath, Sussex. Mr. Scaplehorn has recently been engaged in National Service, from which he has now been released; his many friends in the horticultural world will wish him success in his new venture.

CROPS AND STOCK ON THE HOME FARM.

DAIRY COWS.

THERE were only ten dry days during the month of December, and with a rainfall of 1.66 inch on the first three days of the present year, dairy cows have had most unfavourable weather to contend with. With such bad weather, and grass in the fields of a soft, sappy nature, it is little wonder that the milk yield is considerably reduced. Where the conditions are in the least favourable the cows should be allowed in the open every day for exercise, bringing them in early for the afternoon milking.

During such unfavourable weather as is now experienced, artificial feeding is valuable. Too many persons contend that extra food is of no value to milking cows, especially in the quality of the milk produced. This theory I do not accept, knowing the good results that follow a judicious system of feeding with hay, cake, and roots.

From ten Guernsey cows we are still making 80 lbs. of butter weekly, which is a sufficient proof of the value of added foods. I am a firm believer in the use of Bibby dairy cake after many years' experience in butter-making. Some adhere to the use of cotton-cake, and while this food is no doubt valuable for increasing the quantity of milk, I know it tends to harden the butter unduly, whereas the Bibby kind produces firm butter, but of a silky texture.

Well-made meadow hay is one of the most

valuable of foods for butter production. Even at £7 15s. per ton it is not wisdom to restrict the use of hay to a low minimum; that is, where the most is required from a limited number of cows.

Now that Drumhead Cabbages are over, Savoys and Brussels Sprouts are desirable foods for cattle. Where these are not obtainable the daily quantity of Mangold should be increased, as the roots now contain more saccharine matter than in November, especially where they have been stored in a dry shed.

Each cow may be given as much as 15 lbs. of Mangolds twice daily, provided care be taken to trim off the soil, roots and tops before putting them through the slicing machine. I prefer to use long hay alone rather than chaffing it with the Mangolds. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

CONDITION OF THE CROPS AND LIVESTOCK.

Of the area intended for Wheat it is estimated that some three-fourths has already been sown. As compared with last year, the area already placed under Wheat varies considerably; in the north and parts of the eastern counties, this work is much more backward, but in the Midlands and west it is generally as forward as last year, or more so. On the whole, there was probably a little less actually in the ground. Sowing of winter Oats and Rye is also rather less, but the area of Beans seems about equal to that of last year. Young crops are everywhere quite satisfactory, except on certain heavy and low-lying land. Seeds are mostly reported to be a strong healthy plant in the eastern counties, but elsewhere they are more variable, promising crops being often interspersed with patchy fields. Turnips and Swedes are generally of satisfactory quality, though there are a few reports from the north-western districts to the effect that they are not always keeping well.

Ewes are generally healthy and in satisfactory condition: the earliest in Dorset are reported to be lambing well. Other livestock have maintained fair condition, considering the frequent rains. The mild weather has allowed of their being kept late on the pastures, which has helped to conserve the fodders, so that prospects of winter keep have somewhat improved during the month.

Labour is still in short supply, but a slight improvement may be noted, and several districts report that it has been sufficient for requirements.

DEMOBILISATION.

The names of over 12,000 agriculturists have been forwarded to the Department of Demobilisation for early release from the Colours as pivotal men in agriculture, and it is understood that the demobilisation of these men will be immediately expedited. Agriculture is now one of the industries open for general demobilisation as regards men who have jobs awaiting them. Unless he has already done so, every farmer should take measures at once to get back any man whom he desires to employ, and who is now with the Forces. The first thing to do is to register such men as having employment ready for them immediately they are demobilised. Men who were in the farmer's employment on or before August 4, 1914, should be registered as "contract" men. Other men who were not in the farmer's employment before the war, but whom he desires to employ now, should be registered as "slip" men. Registration can be made at any Employment Exchange. There are forms specially prepared which may be filled up at the Exchange. However, it is not absolutely essential that these forms should be used by farmers desirous of registering men through the post. All that need be done is to write out and fill in the date and signature to the following declaration, and send it to the nearest Employment Exchange:—

"I/we (full name and postal address of employer) hereby declare that (full name and naval or military number and address of employee) was in my/our employment before August 4, 1914, and that I/we are prepared to offer him employment as a (name and occupation) immediately on his return to civil life (or give the date after which the employment will be available)."

Farmers should write the name and other particulars of the man to be registered, and also their own name and address as plainly as possible, and should refrain from adding to the information required any irrelevant matter. If the declaration here given is carefully and accurately filled up and sent to the Employment Exchange, the farmer may rely upon the matter receiving immediate attention.

The above applies to men who were in the farmer's employment before the war. In the case of other men he desires to employ he should obtain a card, E.D. 406, from the Employment Exchange, complete it with the man's particulars, and return it to the Exchange.

Under an Army Council instruction all agriculturists serving at home, whatever their medical category, may be attached to Agricultural Companies pending their demobilisation. All men on agricultural furlough are so to remain until demobilised. These arrangements, which should greatly assist farmers, have already made available for agriculture over 10,500 men.

Obituary.

Thomas Alexander Morris.—The late Mr. Thomas Alexander Morris, whose death occurred on December 10 last, was one of the senior

THE LATE THOMAS ALEXANDER MORRIS.

partners in the firm of Protheroe and Morris. He was the son of the late Mr. T. A. Morris, of Shacklewell, and nephew of the late Mr. G. F. Morris and Mr. W. H. Protheroe, the former seniors of the firm. He resided with his grandfather, Mr. Alexander Protheroe, one of the originators of the firm, at Leytonstone, and entered the office for a few years on leaving school, and then gained further commercial experience in the City, rejoining the firm as a partner at the beginning of 1889, together with Mr. H. G. Morris (son of Mr. G. F. Morris) and Mr. J. B. Slade. Mr. T. A. Morris had just reached his 60th birthday a few days before his death, and 30 years of partnership. He was well known as an auctioneer in conducting sales in the firm's auction rooms, and also at nurseries in different parts of the country, particularly at the annual trade sales, and enjoyed the personal friendship of many well-known horticulturists. His son, Mr. A. G. Morris, was admitted a partner a few years since, which enabled the late Mr. T. A. Morris to take a little more relaxation, but at the outbreak of war his two sons, as well as the sons of the older partners, all joined the Army, and then Mr. Morris devoted his whole time to the business again. He had a breakdown in health at the end of May last, and after recovering somewhat went into the country, where he made progress. It was hoped that this improvement would have continued, and that he would have been able to return, but he had a relapse and passed peacefully away. The late Mr. Morris was for a time on the Committee of the Royal Gardeners' Orphan Fund.

Robert Brown.—We regret to record the death, which occurred on Saturday, the 4th inst., of Mr. Robert Brown, of Yew Tree House, Portbury, senior partner of the firm of Brown and Sons, seedsmen, 31, Bridge Street, Bristol. Though in his 87th year he enjoyed good health until quite recently, and took a keen interest in parochial matters. When living at Failand he was a member of the Long Ashton Board of Guardians for several years. After moving to Portbury he devoted his attention to the affairs of that parish, and was chairman of the Parish Council at the time of his decease. For many years he was a member of the Royal Agricultural Society and the British Dairy Farmers' Association. His remains were laid to rest in Portbury Churchyard on the 10th inst.

GARDENING APPOINTMENTS.

Mr. F. J. Bye, for the past 3 years and 7 months Gardener to C. B. G. GABRIEL, Esq., Coxhill House, Chobham, Surrey, as Gardener to D. PETRIE, Esq., Anningsley Park, Ottershaw, Chertsey, Surrey. (Thanks for 2s. for R.G.O.F. box.—EDS.)

Mr. William Brooks, for the past 12 years Gardener to the late PEMBROKE SCOTT STEPHENS, K.C., Little Missenden House, Buckinghamshire, as Gardener to the Misses CARRINGTON, The Abbey, Great Missenden, Buckinghamshire.

Mr. Lancelot Barker, for the past 7½ years Gardener to C. J. FLIGHT, Esq., Southdown House, Shawford, Winchester, and previously Foreman to GOODWYN HALL, Esq., The Manor House, Alton, Hampshire, as Gardener to Mr. and Mrs. COLE, West Woodhay House, Newbury, Berkshire. (Thanks for 2s. for R.G.O.F. box.—EDS.)

ANSWERS TO CORRESPONDENTS.

COLOUR IN FORCED RHUBARB: *E. M. E.* The reason why stalks of Rhubarb forced in the dark are of a bright red colour is that in the absence of light the chlorophyll, or green colouring matter, is not developed, consequently the red sap colour comes into greater prominence. Where there is no sap colouring present the growths developed in the dark are white, as in the case of Seakale or Potato sprouts. Some varieties of Rhubarb have much more red colouring when forced than others.

GREENHOUSE FLOWERING PLANTS FROM SEEDS: *J. H.* A complete list of annual and perennial flowering plants suitable for greenhouse and conservatory decoration, and capable of being raised from seeds, would occupy considerable space. Such a list would not be of much service unless you have exceptional facilities and exceptional demands for flowering plants, so we append a selection of suitable kinds. Of annuals and biennials the Clarkias, Celosias, Balsams, Browallia demissa (elata), Stocks, Campanulas, Chrysanthemums of the coronarium and carinatum groups, Collinsias, Linum grandiflorum, Nemesia, Rhodanthe Manglesi, Stocks, Nicotiana Sanderae, Salpiglossis, and Schizanthuses in variety are suitable. Perennial plants which may be raised from seeds include Begonias (tuberous and fibrous rooted), Streptocarpus, herbaceous Calceolarias, Cinerarias, Cyclamen, Gloxinias, Petunias, Primulas sinensis (in variety), obconica, verticillata, floribunda and japonica; Salvias and Torenias. Many of the subjects usually propagated by means of cuttings are readily raised from seeds. Any of our advertisers will send you a seed catalogue free on application.

NAMES OF APPLES: *E. C. K.* 1, Cellini; 2, not identified; fruit out of condition.

NAMES OF PLANTS: *J. A. J.* Quercus Ilex var.

MARKETS

COVENT GARDEN, January 15.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

Mimosa, per pad ..	18 0-21 0		

REMARKS.—The conditions in the market are practically unchanged from last week. Chrysanthemums are chiefly confined to "bunch spray" white varieties, which are gradually decreasing in quality as well as quantity. Carnations appear to be getting fewer, especially coloured blooms. Daffodils are more plentiful, with an improvement in quality, and easier prices. Consignments from France and the Channel Islands were very irregular last week. Paper-white Narcissus is arriving in good condition from France, with an increased quantity of Mimosa, Anemones, and Ranunculus. Yellow Narcissus, Paper-white Narcissus, Freesia, Violets, and Daffodils are arriving in fine condition from Guernsey and Scilly, although the consignments are uncertain in arrival.

Herbs, per doz bun.	2 0- 4 0	Watercress, per doz	0 10- 1 0

REMARKS.—The crop of Muscat Grapes is finished: supplies of black Grapes are about equal to the demand. Forced vegetables available include Tomatos, Mushrooms, Dwarf Beans, Asparagus (English and Continental), New Potatos, Cucumbers, Seakale, Rhubarb, and Mint. All seasonable outdoor vegetables continue to be fairly plentiful. *E. H. R., Covent Garden Market, January 15, 1919.*

THE WEATHER.

THE WEATHER FOR DECEMBER.

The first half of December was dull and mild, the second fortnight brighter, but cold. Rain or snow fell on 20 days, yielding a total of 1.52 inch, the heaviest fall on one day being 0.34 inch on the 22nd. Of sunshine we had 52.9 hours, being an average of 1.7 hour per day, and a percentage of 22.5. The 31st was the brightest day with 5.4 hours. With a mean of 29.60 inches the barometer varied from a highest of 30.05 inches on the 15th to a lowest of 29.04 inches on the 23rd. The mean temperature for the month was 38.5°, with a highest maximum of 55° on the 1st, and a lowest minimum of 23° on the 26th. This gives an absolute range of 32°. On the 29th we had the lowest maximum of 35°, and on the 2nd the highest minimum of 46°. The mean maximum was 44°, and the mean minimum 33°, giving a mean range of 11°. On eighteen nights the temperature fell below the freezing point, but rose above that point on every day. The mean minimum on the grass was 28°, with a lowest of 19° on the 20th. There were twenty nights of ground frost. At 1 foot deep the soil temperature rose from 38° to 43°, and then fell to 34°. Light winds prevailed during the month, chiefly from the west and south. A fine display of aurora was observed on the 25th.

THE WEATHER IN 1918.

Expressed in averages of temperature, rainfall and sunshine, the weather of 1918 shows no marked deviation from the normal, yet the weather of 1918 had its own special features. Averages but mask the vagaries of weather as they certainly reduce its extremes. Thus the opening month of the year, with its mean temperature of 34°, had a range of 43°, from a highest of 52° on the 24th to a lowest of 9° on the 14th, while the same month in 1917, with a mean of 35°, had but a range of 30°. Snow fell frequently in January and lay continuously from the 6th to the 19th. In February we had a blizzard on the 29th, the snow lying till March 5. April had a five-hours snowfall on the 22nd, and May opened with a fall of one hour's duration. There were no abnormally warm days during the summer, the highest temperature recorded being 76°, on June 1. Thunderstorms occurred in May, June, July and August, that of May 22 being severe. Gales, chiefly from the west and south-west, were frequent, one on June 14 doing some damage to the vegetation in the district. Persistent and heavy rimes were a feature of November, while the first snow for the season fell on December 22.

Temperature.—The mean temperature for the year was 46°, being a fraction of a degree over the average for 1916-18. August had the highest mean temperature of 57.5°, and January the lowest mean of 34°. The highest maximum was 76° on June 1, and the lowest minimum, 9°, on January 14. During the past three years the highest maximum was 82° on August 5, 1916, and the lowest minimum, 8°, on March 9, 1917.

Rainfall.—Of rain we had a total of 25.20 inches, the average for the past three years being 30.93 inches. April and June had the lowest rainfall, of 0.85 inch each, and July the highest fall, of 4.63 inches. The most rain collected on any one day was 0.87 inch, on September 15. Rain or snow fell on 200 days during the year, 124 of these being official "rain days" of 0.04 inch or more.

Sunshine.—Bright sunshine was registered on 282 days, with a total of 1,418.2 hours. This gives an average of 3.9 hours per day, and a percentage of 29. The total is 84.6 hours over the average of the two previous years. The relatively brightest month was April, with 44 per cent of the possible, while March and October were the relatively dullest months, with 21 per cent. each. June had the greatest number of hours of bright sunshine, viz., 228.6, and January the lowest number, viz., 52.5. *James Malloch, St. Andrews Training College Gardens, Kirkton of Mains, Dundee.*

CATALOGUES RECEIVED.

SEEDS.

ROBT. VEITCH & SON, 54, High Street, Exeter.
FISHER, SON & SIBRAY, LTD., Royal Nurseries, Handsworth, Sheffield.

JEFFERIES' HYBRID GLADIOLI. English raised and English grown. For massing, few flowers can equal the magnificent display made by our beautiful Hybrid Gladioli, during the months of July, August, and September. Our strain the result of careful hybridising, is altogether superior to the ordinary mixture, usually of Continental origin, offered by the trade. The flowers vary in colour, from pure white, through shades of lemon, yellow, orange, salmon, to deep blood red and purple, the pleasing art shades of orange and salmon predominating.

Secure your bulbs at once; they are scarce, and will be difficult to procure later on.

Strong flowering bulbs, per 100 17s. 6d., per 1,000 £8, carriage free for cash with order.

JOHN JEFFERIES & SON, LTD., Royal Nurseries, Cirencester.

EVERY WEEK

(principally on Wednesdays).

Catalogues forwarded. Commissions executed.

FOR SPECIAL OFFER. IMMEDIATE DISPOSAL.

A LARGE TRADE STOCK of ESTABLISHED ORCHIDS, comprising

50 ONCIDIUM ROGERSII, 30s. per dozen.

250 CYPRIPEDIUMS, superior decorative types, hybrids of Leeanum, &c., very good plants, in variety, 42s. per dozen.

100 ODONTOGLOSSUM GRANDE, smart plants, in two sizes, 30s. and 60s. per dozen.

300 CATTLEYA GASKELLIANA, fine plants, in 6in. pots, 2 and 3 leads each, 60s. per dozen.

300 CATTLEYA and LAELIO-CATTLEYAS, HYBRIDS, good plants and useful decorative varieties, in 6in. pots, 48s. per dozen.

500 CATTLEYA and LAELIO-CATTLEYA SEEDLINGS (unflowered), of very choice parentage, purchased from the "Brackenhurst" collection, nice sound plants, mostly in 2in. pots, 20s. per dozen.

2,000 ODONTOGLOSSUM CRISPUM, smart plants, in 4in. and 5in. pots, £12 per 100.

2,000 ODONTOGLOSSUM CRISPUM, nice plants, in 3in. pots, £6 per 100.

5,000 ODONTOGLOSSUM CRISPUM, small plants, healthy and sound, many unflowered, 50s. per 100.

These Od. Crispum are the best type, the famous and beautiful Od. Crispum "Solum," and Od. Crispum "Queen Empress," and others having originated from this stock.

The above is a specially cheap offer, as the plants must be cleared immediately, thus affording a most favourable opportunity to buyers desirous of replenishing stocks, as no importations from abroad are likely to arrive for some time.

Specially favourable terms to large buyers.

Full particulars from and all inquiries to A. J. KEELING & SONS, Westgate Hill, Bradford.

Supplied by all Seedsmen and Nurserymen.

Per cwt., 30/-; 56 lbs., 16/-; 28 lbs., 9/-; 14 lbs., 5/-. Also in Tins, 9d., 1/3, and 3/-.

Sole Manufacturers: **BULL'S PLANT FOOD CO. 536, KING'S ROAD, CHELSEA, LONDON, S.W. 10.**

Let Ryders Stock your Kitchen Garden.

Food prices have shown very little decrease. It is just as important as ever to sow Ryders Seeds in the garden or allotment and thus assure yourself of ample supplies of vegetables of quality and freshness.

Ryders have been preparing for many months in order to be able to offer comprehensive stocks of the world's finest seeds.

Experience has taught hundreds of thousands of gardeners and allotmenteers that it is wise to "Rely on Ryders," and the demand for Ryders Seeds, enormous as it has been, will be greater than ever this season.

RYDERS SEEDS

still at $1\frac{1}{2}$d. per packet.

Send for a Copy of Ryders Catalogue now.

It is a publication which no cultivator can afford to miss. You will find in it full particulars of **RYDERS 1919 VEGETABLE COMPETITION.** Last season's Competition was an enormous success. This season there will be Three Cash awards in each Class.

THE FOOD OF WORMS.

THE subject of the food of worms is one of prime importance to the gardener, the florist, and the farmer. As such it has received a considerable amount of attention on the part of scientific observers during the past few years. Yet, in spite of all that has been done and written, the question is still persistently put; What do worms eat? Do they really feed on the dead leaves which are dragged into their burrows? Or do they feed on soil, on other animals, or on living plants?

In as much as I have been working on this subject during the greater part of the past four years at the Birmingham University, the following account of our knowledge may be of interest.

Some people believe that worms "simply make tunnels in the earth as a mole might do, thrusting aside the soil, but never passing it through their bodies. The leaves are used to line the burrows. The real food of the earthworm is not mineral or vegetable, it is animal; and consists of those minute creatures which live in the soil, and are known as amoebae." Which of these views is correct?

On the face of it one might suppose that it would be sufficient if we collect those little pellets of earth which, under the name of worm-casts, are found bestrewing our lawns and disfiguring our paths. Let samples of these be taken, placed in a petri dish, or on a plate and mixed with a little water. What do we find? A fine, often unctuous, blackish mould, full of tiny quartz granules, bits of vegetable fibre, and all those other constituents which go to make up what we generally call vegetable mould. Has not this passed through the body of the worm? Are we not dealing with true excreta? And do not the different ingredients show that both vegetable and mineral matter have been taken into the body of the creature which cast it up?

The natural objection would be that contamination, adulteration, and admixture have taken place. In passing through the upper layer of soil the "cast" has come into contact with various earthy and other matters, and it is therefore impossible to pass a true judgment. The objection is valid, to a certain extent. So we take a well-fed worm from the earth, as we might take a pigeon or pheasant to examine its crop. If we allow it to void the matter which fills the intestinal tract, what shall we find? That the extruded matter is a fine soil, composed, as we have already found, of finely macerated vegetable matter mixed with grit and oozy soil, and held together by a slimy secretion from the worm's intestine.

Let us now attack the subject from a second position. We have all seen leaves around the burrows of worms in autumn, and have watched their gradual disappearance. Let us venture to intrude into the worm's burrow, and look for the lining of leaves. They are nowhere to be found. And if now we will turn to the classical work, *Vegetable Mould and Earthworms*, by C. Darwin, or any of the more recent researches on the subject,* we shall find that those who are best able to pronounce an opinion are agreed that worms feed on vegetable matter and soil.

But we may go further. It is a commonplace in biology that animals are organised in harmony with the food on which they chiefly depend. The carnivore has teeth, while the parasite which lives on the peptonised juices of its host is destitute of them. How is the worm placed with respect to this digestive furniture? I quote from Darwin, because he is easily accessible, and his authority will not be challenged:—

"The mouth is situated at the anterior end of the body, and is provided with a little projection (lobe or lip, as it has been variously called) which is used for prehension. Internally, behind the mouth, there is a strong pharynx, which is pushed forward when the animal eats, and this part corresponds, according to Perrier, with the protrudable trunk or proboscis of other annelids. The pharynx leads into the oesophagus, on each side of which in the lower part there are three pairs of large glands, which secrete a surprising amount of carbonate of lime. These calciferous glands are highly remarkable, for nothing like them is known in any other animal. . . . . In most of the species, the oesophagus is enlarged into a crop in front of the gizzard. This latter organ is lined with a smooth, thick chitinous membrane, and is surrounded by weak longitudinal but powerful transverse muscles. Perrier saw these muscles in energetic action; and, as he remarks, the trituration of the food must be chiefly effected by this organ, for worms possess no jaws or teeth of any kind. Grains of sand and small stones, from the 1-20th to a little more than 1-10th inch in diameter, may generally be found in their gizzards and intestines. As it is certain that worms swallow many little stones, independently of those swallowed while excavating their burrows, it is probable that they serve, like millstones, to triturate their food" (*op. cit.* 17-18).

*Vide.—A Contribution to the Bionomics of English Oligochaets, by the present writer; "Science Progress," July, 1913, Vol. VIII., 99-112.

As the subject is important we may add a few (condensed) lines from the section dealing with *Food and Digestion* (p. 35 *et seq.*). "Worms are omnivorous. They swallow an enormous quantity of earth, out of which they extract any digestible matter which it may contain. They also consume a large number of half-decayed leaves, petioles, peduncles, and decayed flowers. But they will also consume fresh leaves, as I have found by repeated trials. They are cannibals, for the two halves of a dead worm placed in pots were dragged into the burrows and gnawed."

The setae of worms are often found in the intestine, showing that a meal had been made of the dead members of the family. Indeed, one has only to dissect a worm and study the contents of its stomach to learn what is the nature of its food.

But the opponent of the statement that worms feed on vegetable matter is nothing if he is not smart. "I grant you," he says, "that leaves and even gritty mineral matter are found in the worm's gizzard My contention is that these are taken up by the creature, not for their own sake, but for the sake of the juicy animalculae which are contained therein." Precisely. As who should say, "A sailor eats ship's biscuits for the sake of the weevils!"

In this connection, it is worth notice that a certain genus of earthworms is denoted scientifically as Dendrobaena, because the species are frequently found living in decaying and fallen timber. If these are examined it will be found that their stomachs are full of wood pulp more or less digested. I do not know of any amoebae on which they could subsist; but certainly the line of investigation is worth pursuing. *Hilderic Friend.*

(To be concluded.)

NOTES ON IRISES.

IRIS LACUSTRIS.

THIS interesting little plant (see fig. 13) belongs to the Evansia section of the genus, being a rhizomatous species with crested falls. It is local in its distribution, and is apparently only found near the southern shores of the great lakes Superior and Huron, where it grows in moist, gravelly soil in half-shady spots near streams.

The accompanying sketch, which was reproduced from specimens sent in November, 1918, by Mr. T. Smith, Newry, shows the peculiar arrangement of the ridges on the falls. There is a central, crinkled white crest, tipped with orange, and this is flanked by two lateral ridges. The colour is a deep purple, with a certain amount of white and paler lilac-purple in the region surrounding the ridges on the falls. The standards are usually more spreading and less erect than those depicted in the sketch.

The slender, greenish-brown rhizome spreads

rapidly, and is capable of flowering at any time from May till October, if the conditions are of its liking, and if there is plenty of food in the shape of humus within its reach.

In order to obtain seeds, artificial cross-fertilisation is usually necessary in this country, and even then the small capsules do not contain a large number. The seeds are peculiar, for, as is shown in the right-hand bottom corner of the sketch, each has an attachment which is actually longer than its own diameter.

This peculiarity is only shared by I. cristata, and it seems better to look upon I lacustris as merely a local form or sub-species of cristata. It is true that I. lacustris, when raised from seeds here, retains its dwarfer habit and the deeper colour in its flowers. Seeds of I. cristata have always refused to germinate here, and it is, I think, the only species the seeds of which, when ripened here and sown at once, have always failed to produce seedlings. My impression is that the colour of I. cristata is apt to vary from lavender to purple, and there is certainly a white form.

If, therefore, we are unable to separate cristata and lacustris except by size and possibly colour, it is probably wiser to refuse specific rank to the latter.

As a garden plant it grows well in conditions approximating to those in which it grows wild. Here, in the dry sand of my garden, I give it old decayed leaf-mould and fine gravel in a position only reached by the late afternoon sun. Every two, or at most three, years I re-make the bed and replant the strongest young shoots immediately the flowers are over. Then root-growth is active, but it ceases altogether in autumn, a period, consequently, at which transplantation is usually fatal. *W. R. Dykes, Charterhouse, Godalming.*

FIG. 13.—IRIS LACUSTRIS: AN AUTUMN-FLOWERING SPECIES.

NOTES FROM AMERICA.

DESCRIPTIONS OF HORTICULTURAL PLANTS.

Now that the war is over, and we are entering upon a period of reconstruction, it seems reasonable to consider whether horticulture may not be put on a more scientific basis. Judging from my own experience, I venture to suggest that we need most of all more exact methods of observing and recording our facts. Anyone who has tried to unravel the history of any horticultural species and its varieties knows how difficult it is to obtain reliable information. Even when the date of introduction to the trade is known, there is usually no definite record of the original discovery or mode of origin of the plants. It is also usually more or less uncertain whether the plant now called by a particular name is exactly the same as that known by the same name years ago. It is not sufficient to preserve herbarium species, as these frequently cannot illustrate many of the important characters. The more delicate shades of flower colour are evanescent or changed in dried plants, and, of course, such characters as earliness, resistance to frost, and flavour, do not appear at all. What we seem to need is a system of describing all new or supposedly new forms, species, or varieties, in exact botanical terms, from the living plants. In most cases, photographs should also be taken, and all historical facts available should be recorded. The materials thus gathered should be published at frequent intervals, as cheaply as is consistent with excellence. Probably the best method would be to print accounts pertaining to different genera on separate small sheets of uniform size, which could later be arranged and bound as desired. Such a method can only be fully successful in the hands of experts, and probably every genus of any importance should have its specialist, to whom all material belonging to it would be referred. The whole scheme involves a rather large expenditure of money and a great deal of intelligent co-operation; but the war has shown us that we can co-operate and can raise vastly greater funds when we want to. There is really nothing to prevent the carrying out of the plan suggested, unless it is the absence of the will to act. Can it be doubted that through it horticulture might become a far more exact science than it now is, with equal benefit to horticulturists and mankind in general?

The following is a convenient method of publication in the proceedings of the Biological Society of Washington; the descriptions are issued in separate form, and can be collected and bound as desired:—

SOME PLANTS FROM NEW MEXICO.

WHEN in the Rito de los Frijoles, New Mexico, last year, I noticed a very beautiful Oenothera, not quite like anything I had seen. As it was too early to obtain seed, I brought home a small living plant in flower and put it in the garden It produced a small amount of seed; but instead of dying, wintered over, and has this year grown to a great size and flowered profusely. It will yield enough seed to supply everyone interested in growing Oenothera, and will afford a new type to use in hybridisation experiments. It seems, therefore, desirable to give it a name.

OENOTHERA HOOKERI HEWETTI subsp. nov.

Plant very large, spreading, about 4 feet high, and spreading 4½ feet; stem and branches red, at full maturity the upper parts of the long branches, while closely beset with fruits, not appearing leafy, the bracts being reduced to less than the length of the capsules; leaves repand denticulate, of the type of O. Hookeri, only very sparsely pubescent, greyish green; upper bracts much longer than fruits, apparently not deciduous; fruits as in the biennis group, but not contracted at apex, greyish, slightly speckled or streaked with red, finely pubescent, with scattered longer hairs intermixed; seeds angled; buds stout, distinctly 4-angled, coloured with red, exactly as in O. rubrinervis as figured by Gates, Zeits. f. indukt. Abst. und Vererbungsl. 1911, IV., pl. VI, f. 4; sepals not separate when reflexed, the tips sometimes free as much as 10 mm.; branches tough and hard to break, not brittle as in O. rubrinervis; calyx tube in fully developed flower 37 mm. long; petals bright yel-

low, turning slightly reddish in fading; petals about 38 mm. long and 40 broad, not distinctly emarginate, though appearing so from folding in the opening flowers; total length of pistil 78 mm., extending about 13 mm. beyond the stamens and about 7 mm. beyond the petals. The tube of the calyx is of the same length as that of O. rubrinervis, but the sepals are about 6 mm. longer.

Abbott Ranch, Rito de los Frijoles, New Mexico, growing in a grove of Populus angustifolia, August, 1912 (Cockerell). Described from living plant in garden at Boulder, Colorado. Named after Dr. W. L. Hewett, the Director of the Archaeological work at the Rito de los Frijoles. It is evidently close to O. irrigua Wooton & Standley, but differs from the description, especially as to the pubescence. Mr. Paul C. Standley kindly informs me that it is very different from the typical form of O. irrigua. It is no doubt an "elementary species," and it may either be placed as a subspecies of O. Hookeri or given a binomial as Oenothera Hewetti.

SEDUM COCKERELLI (Britton).

Last August I collected living plants a few miles from the type locality, and now have them flowering in my garden. The characters "petals white, anthers pink," were given by Doctor Britton from my recollection. It now proves that the anthers are only slightly flecked with pink; it is the styles that are bright pink. The white petals have a transverse pink blotch near the middle. The plant is glabrous but scurfy. Stems light green; stem-leaves narrower at base than beyond, and not very acute.

HELIOTROPIUM XEROPHILUM (Cockerell).

In the new Illustrated Flora and elsewhere H. spathulatum Rydberg is given as a valid species, ranging to Chihuahua. It is, I am confident, H. xerophilum, described the year before. I think it is certain that there is only one species of the H. curassavicum group in New Mexico and Chihuahua.

T. D. A. Cockerell, Boulder, Colorado, Dec. 5, 1918.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM VICTORY.

THIS superb variety has flowered with R. Brooman-White, Esq., Arddarroch, Garelochhead, N.B., who states that it is by far the best Odontoglossum that has appeared in his collection, which, however, contains specially fine forms of O. crispum. It is of the true Pacho type, and has flowered on a previous occasion, when the plant was not so vigorous, and these early flowers were not equal to those produced now on a nine flowered inflorescence.

The flower is perfectly round, 4½ inches in diameter; white, with a faint tinge of pink on the sepals. The petals are broad, overlapping the sepals, and the lip more than usually ornate.

BLUE DISAS.

IN his note on "Blue Orchids" (p. 1), Sir Jeremiah Colman confined himself to plants that can be grown successfully in gardens, otherwise he would surely have included the lovely blue Disas of South Africa. They have been tried again and again as garden plants in this country, but without success. Mr. N. E. Brown, writing in *Gard. Chron.*, Aug. 1, 1885, p. 135 *et seq*, says the reason why these Disas are not grown may be that after flowering the plants fail to appear again the following season, and that how far this is due to natural causes, not understood, and how far to ignorance of the proper method of treatment, remain to be discovered.

When I was at Cape Town in 1887 I heard much about the blue Disas of Table Mountain, and I planned an excursion to see them growing there, but this had to be abandoned, as during the few days at my disposal, the "table cloth," a dense white fog which spreads over the top of the mountain when the wind is in a certain direction, made the climb too hazardous. I had the pleasure, however, of seeing the Disas and other beautiful flowers which had been gathered by flower-sellers, who hawked them about in Cape Town, and I purchased several bunches of them, which afterwards adorned the table of the saloon of the steamer on which I returned to England. That was in February, when most of these flowers are at their best on the mountain. Disa graminifolia, also called Herschelia coelestis, was the pick of the lot, and if a bunch of its flowers, such as I possessed, could be shown in London, blue Disas would be in demand. The species named has long, grass-like leaves, slender stems 18 inches to 2 feet long, and flowers in racemes of from 3 to 6, each over an inch across, and of an intensely bright and beautiful blue in as many shades as there are in the flowers of Gentiana sino-ornata. Bolus, in *The Orchids of the Cape Peninsula*, states that it is one of the commonest species, has a rather long flowering period, and attracts universal observation by its beauty and brilliancy. Dr. Lindley described it as "species laec pulcherrima, colore coeli australis intense coeruleo superbiens." I secured a potful of tubers from the Botanic Gardens at Cape Town, and brought them, together with my other "finds" to Kew, but only one developed a spike, and that a poor one. We have received tubers several times since, but have had no success with them. Should this meet the eye of anyone in Cape Town interested in sending choice plants to England, I hope he will send tubers of this Disa to Sir Jeremiah Colman, Gatton Park, Reigate, where Orchids more or less refractory are conjured into putting forth their best.

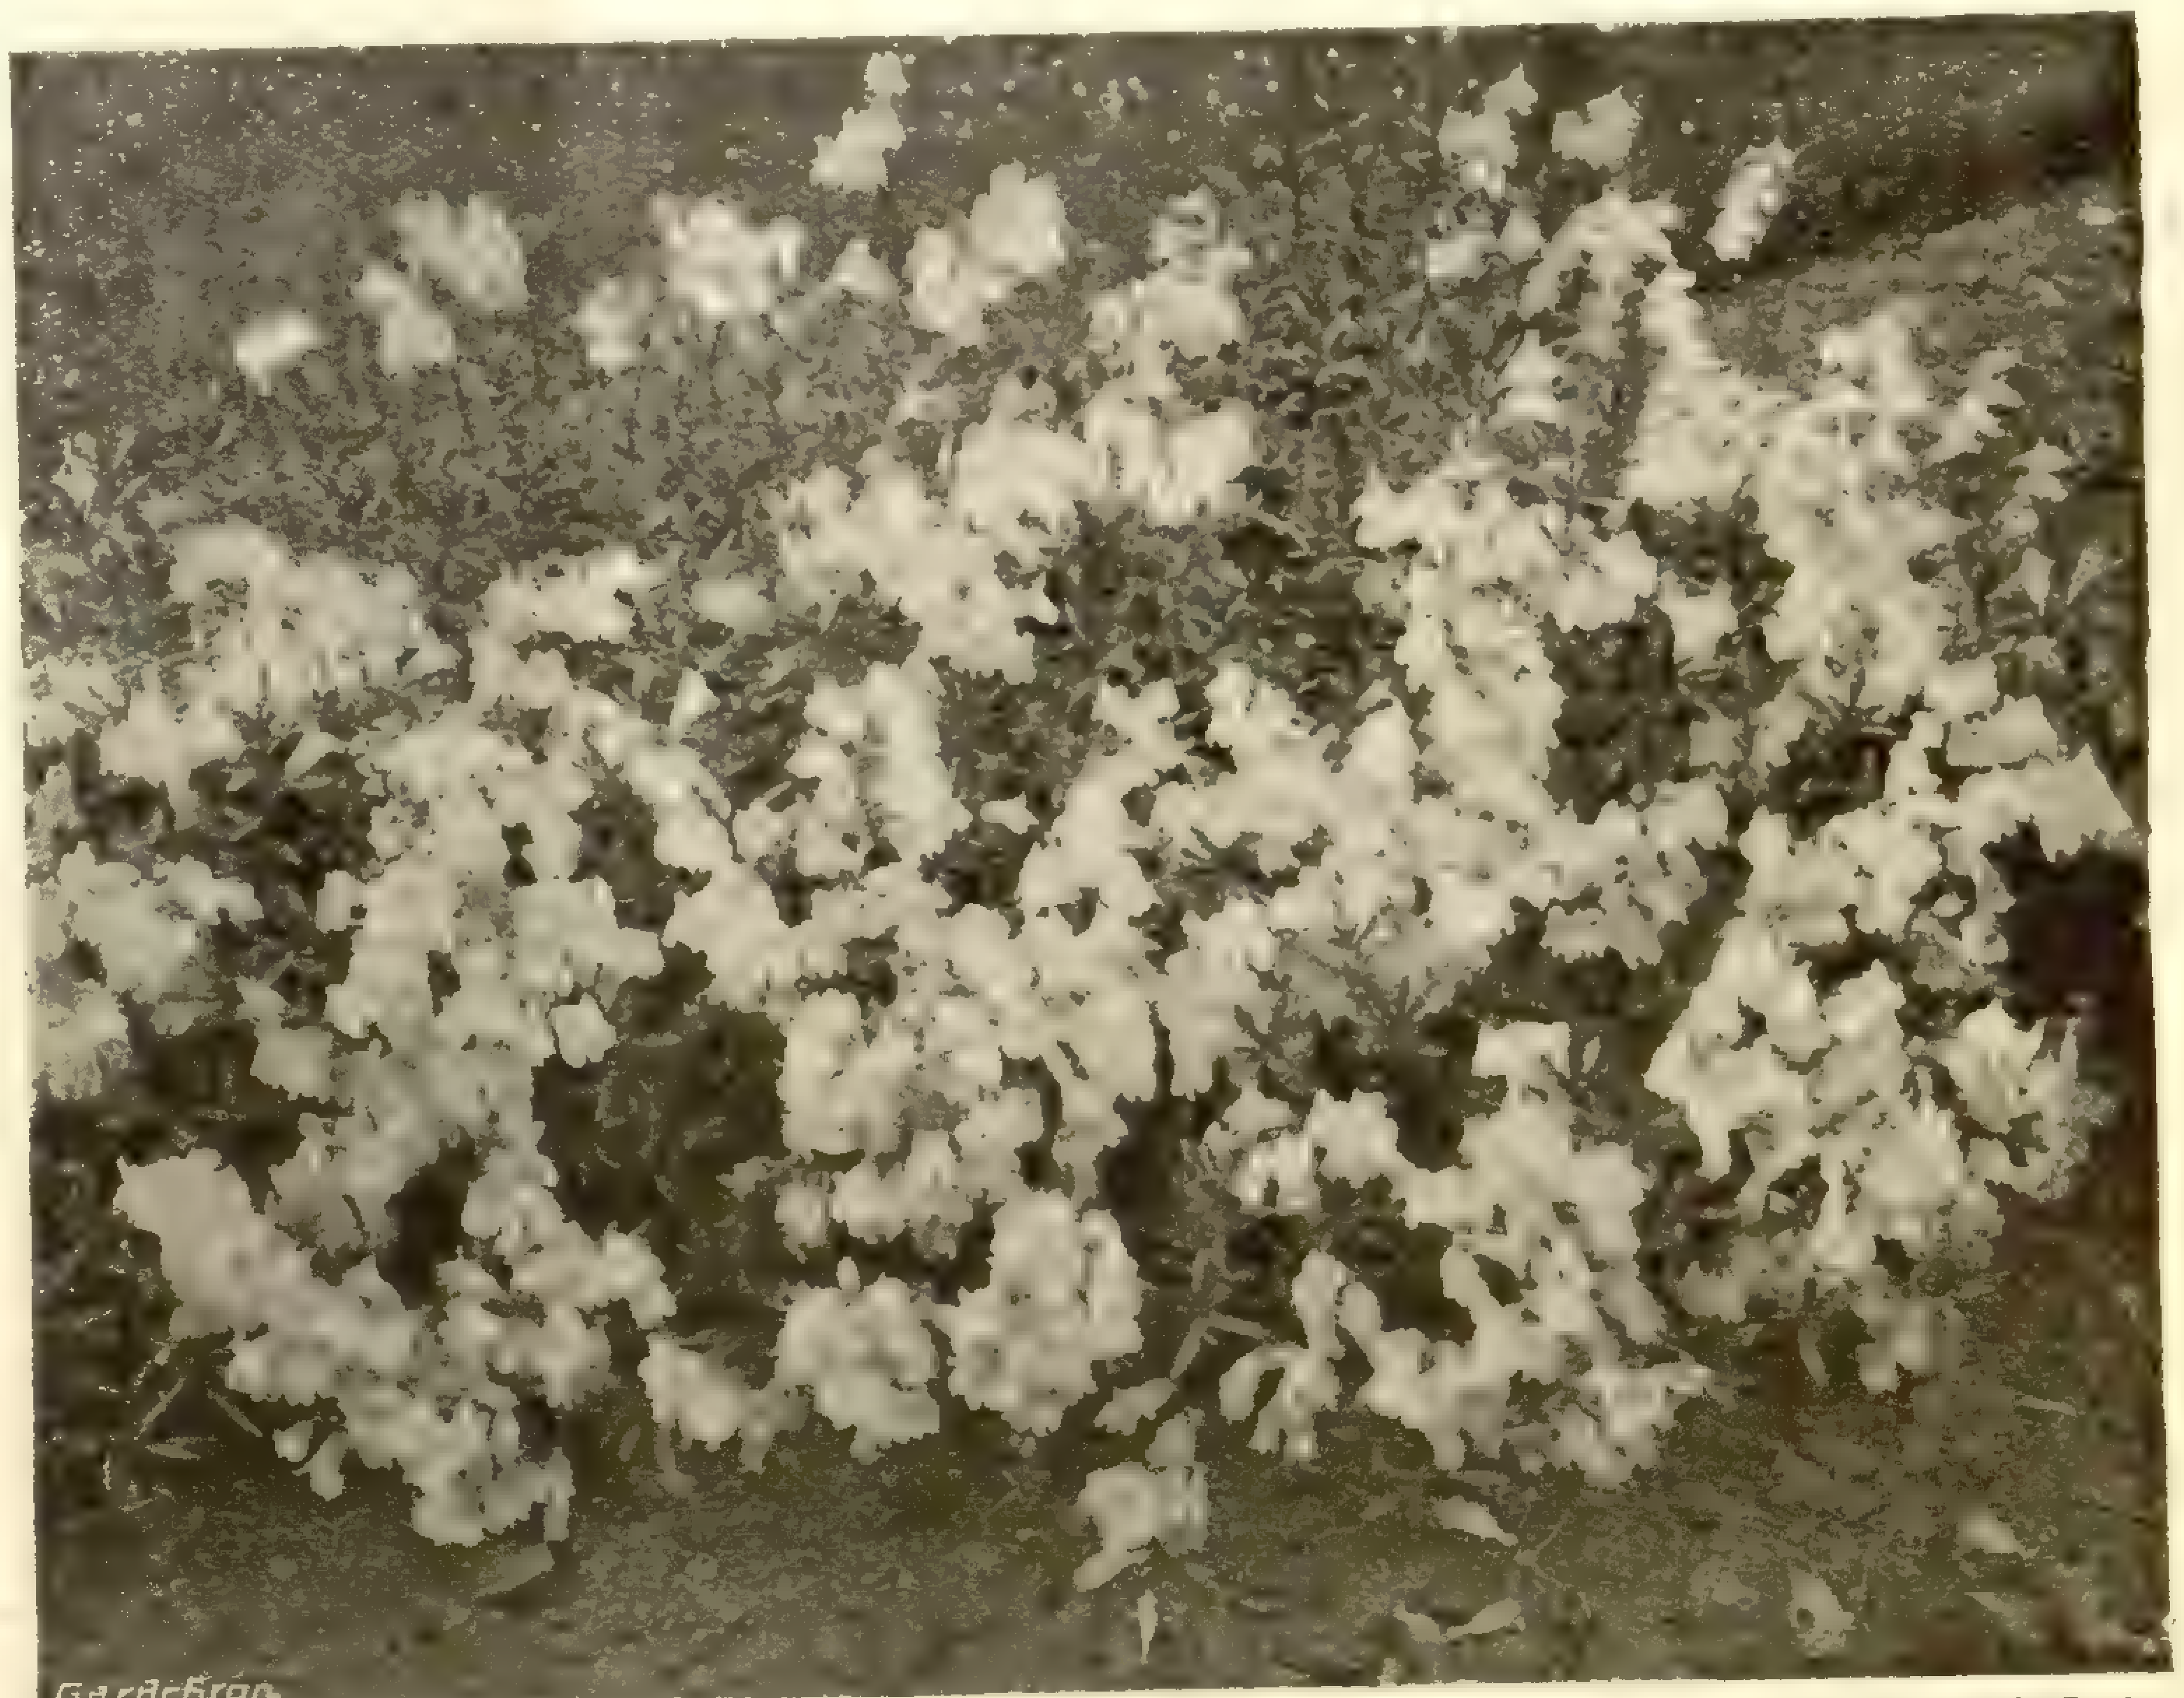
Other species of Disa that grow in South Africa and have blue flowers are D. longicornu, D. maculata, D. purpurascens, and D. venusta. These also are worth introducing into this country. They flower in our winter months, which are those of summer in Cape Town, and it may be owing to this fact that they do not thrive here. Many plants, as we know, flower by the calendar, and cannot be induced to change to fit our seasons. Orchids are particularly stubborn in this respect. *W. W.*

HARDY FLOWER BORDER.

PENTSTEMON SCOULERI.

THIS handsome Pentstemon (see fig. 14) has been usually considered to be a variety of Pentstemon Menziesii, a species which embraced several apparently closely allied forms. In a recent revision of the genus some of these forms have been accorded specific rank, and among them the plant under notice. Of the others, what was formerly known as the variety Lewisii has been made a species under the name of P. fruticosus, and var. Douglasii a species under the name of P. crassifolius. These alterations are justified in view of the great range of variation met with in the different plants formerly included under the name of P. Menziesii. The type of this species is a small, prostrate, creeping plant, with sub-shrubby stems, which produce roots from the nodes as they grow; very small ovate leaves, and rosy purple flowers. P. fruticosus is of erect, shrubby habit, with larger obovate leaves and rosy purple flowers. Next in the series is P. crassifolius, with narrow, lanceolate leaves and lilac purple coloured flowers, then follows P. Scouleri, a free-growing, shrubby species, often forming bushes 2 or 3 feet across and 1½ foot to 2 feet high. The twiggy branches are well clothed with lanceolate leaves about 2 inches long, and the whole plant bears a profusion of violet purple flowers in May, larger than in the preceding species. Its native habitat is in rocky crevices at fairly high elevations in Oregon and British Columbia.

This Pentstemon is an easy plant to cultivate and propagate; cuttings strike readily in the autumn, while the species is quite hardy when planted in sunny, well-drained situations. *W. I.*



[*Photograph by W. Irving.*

FIG. 14.—PENTSTEMON SCOULERI: FLOWERS VIOLET-PURPLE.

CULTURAL MEMORANDA.

MULCHING NEWLY PLANTED FRUIT TREES.

IT is the custom of many planters to apply a mulching of well-decayed manure at least 3 inches thick, around newly planted fruit trees, as though the trees were tender subjects and needed protection. I was once an advocate of this practice, but now see how useless and injurious it is. If those who disagree with my condemnation of the custom of mulching newly planted trees in November will examine the soil under the manure, especially if heavy and naturally retentive of moisture, in March, they will find it a cold, sticky, uninviting medium for surface-roots. Soil so covered cannot become warmed by the sun or drying winds, and air is excluded. A mulching for newly planted trees is an advantage if applied in April, May, or the following months, after the sun has warmed the soil, as it reduces the evaporation of moisture and encourages the development of surface roots. The mulching should be of half-decayed horse manure spread 3 inches deep. *M. B. W.*

LETTERS FROM SOLDIER-GARDENERS.

A CHÂTEAU GARDEN IN FRANCE.

DURING my two years in France (now happily ended), I never missed an opportunity of inspecting all gardens, large and small, that were within easy distance. As my time there was spent in the forward area, except for the brief periods when we came back on what is, with grim humour, called "rest" (but which too often would be better described as intensive training), my opportunities for observation were very limited.

I am giving away no military secret when I state that the garden which I now attempt to briefly describe is situated not far from the city of St. Omer. The château had been vacated, and was used as the temporary headquarters of a field ambulance. As is the case with many French châteaux, it stands fairly close to the road, with a small front garden and a large garden at the back. There is nothing in the garden which deserves special mention, except that it is typical of those attached to what I might call the lesser châteaux of France. These gardens incline far more to the useful than the beautiful, and they fulfil in a larger degree than most English gardens the real purposes of a garden, which should be primarily the supply of fruit and vegetables for the household. Even in the front garden we find fruit trees, such as standard Plums and espalier Apples and Pears. A feature of the front garden, as indeed of many villa gardens in France, is the large clumps of Rhubarb, which are evidently planted for ornament as well as for produce. Roses in beds were also a feature, but, as the season was late, there was no chance of determining the varieties. On one wall of the château was a Vine, but in the North of France there is evidently the same difficulty in growing Grapes out-of-doors as there is in England. Other fruits, such as Apples and Pears, covered the walls of the château, but these were mainly furnished with creepers. Grass and flowers separated the house from the kitchen garden. The vegetable garden was laid out as a parallelogram and intersected with walks. At a distance of a few feet from the central dividing path on either side was a fence supporting espalier Apple and Pear trees, and distant about 6 feet from these fences was a secondary line of espalier fences. Between the fences the space was filled with two rows of Rhubarb. The narrow borders skirting the walks were planted mainly with such flowers as Pinks, but in some cases also with herbs and salads. The outer borders of the food garden where it drifted informally into the flower garden were of greater width, and were used as mixed flower borders. The arrangement gave no impression of artistic skill in floral planting, but the effect as gathered from the late flowers could certainly not be described as displeasing.

The crops more largely grown in the food garden were Haricot Beans, Savoys, Leeks, and evidently a fair breadth had been allotted to Potatos. Leeks are largely grown in all French gardens, but seldom did I see them so large as those grown in Britain. They are planted much more closely together, and are not earthed up. A line of tall trees of Mountain Ash ran down one end of the vegetable garden, and immediately behind these was an archway of Hazel overcircling a gravel path. On the other side the garden was bounded by an irregular belt of shrubs, the foreground of which was utilised for Dahlias and hardy herbaceous plants.

Small fruit intersected the main plots, and there were several large trees of Apples, Pears, Plums, and Cherries. As intimated before, the main part of the garden was devoted to growing food, but this was not shut off from the flower garden, as is so frequently the case in English gardens. *William F. Rowles.*

TREES AND SHRUBS.

HYBRID OAKS.

THE *Journal of Heredity* for October, 1918, contains an account of Oak hybrids raised by H. Ness, Horticulturist to the Texas State Experiment Station. The parents used were the Overcup Oak, Q. lyrata, and the Live Oak, Q. virginiana, the latter being the mother. Both belong to the Lepidobalanus subdivision of the genus, though they differ widely in a number of features. The Live Oak has a low trunk and a broad, diffuse head of rather crooked limbs and shoots, while the Overcup Oak is of a tall pyramidal form with straight branches and shoots. The foliage of the Live Oak persists through the winter; the Overcup is one of the first to shed its leaves in the fall. In the Live Oak the leaves are relatively small, more or less elliptical, and entire; in the Overcup they are much larger and deeply lobed. But perhaps the most marked difference lies in the Acorns. In the Live Oak these are ovate and project about two-thirds of their length beyond the cup; in the Overcup, as the name suggests, they are oblate and nearly covered by the cup, the scales of which are much thickened. The hybrids raised, seven in number, were very uniform. In general habit the father, with its pyramidal form and straight shoots, was dominant. The leaves were intermediate in size, but resembled those of the father in being lobed. The form of the Acorn, however, was very like that of the Live Oak, though larger in size. The leaves of the hybrids commenced to fall in the winter, but many of them remained green until the spring. In this feature, therefore, the hybrids were intermediate. An interesting point is that hybrids like these have been found sometimes growing in the natural state, and were described recently by Professor Sargent under the name Q. comptonae. Apart from their scientific interest, it seems not unlikely that they may prove to be of value from an arboricultural standpoint. They grow rapidly, the earliest raised having reached a height of 16 feet in 8 years from the time of sowing, with a diameter of 5 inches a foot from the ground. Owing to the density and lustre of their foliage they are superior to both of their parents as ornamental trees. The wood is very hard, close-grained, and tough.

NOTES FROM FRANCE.

WHITE POGONIRIS.

To the very complete study of White Pogoniris published in *Gard. Chron.*, November 23, 1918, I would add the very fine variety named La Neige, obtained by the late Mr. Verdier in Paris some fifteen years ago, and placed in commerce by Messrs. Vilmorin. Of its parentage I can say nothing, but it is one of the very best white Irises, not only because its flowers are quite pure, but also on account of the falls being so thick and of so good a substance as to stand out horizontally, and last longer than those of any other variety. *S. M.*

BEGONIA EVANSIANA.

To the note on this Begonia published in *Gard. Chron.*, November 23, 1918, p. 209, I may add that it has long been grown in France for summer bedding, where it grows as finely as the plants illustrated in fig. 82, 1918. It is considered hardier than the hybrid, tuberous-rooted Begonia erecta. So hardy is it, indeed, that I have seen some tubers, forgotten in the beds, and protected by dead leaves which have fallen by chance upon them, survive in mild winters. But the plant cannot stand the sun; the more shady and cool its position, the better it grows. *S. Mottet.*

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Forcing Potatos.—A few early Potatos may be grown either in 10-inch pots or herring-boxes; these receptacles may be easily moved to a cooler house when the temperature of the one in which they were started becomes too high. If the sets have formed healthy sprouts by standing them in boxes they will be in the best possible condition for planting. Here we place three sets in each 10-inch pot and box. Use a friable compost consisting of loam, leaf-mould, and well-decayed manure, the material from a spent Mushroom-bed being suitable. Allow room in the pot or box for applying a top-dressing of fresh compost when the haulm is about 6 inches high. When potted, grow the plants in a Peach house or vinery that has just been started. May Queen, Harbinger and Express are good varieties for forcing.

Main Crop and Late Potatos.—Stand the seed tubers of main crop and late Potatos in boxes, or on light stages, before they make "blanched" and weakened growths. Let the tubers have plenty of light and guard against injury by frost.

Peas.—A few boxes may be sown with Peas, using similar compost to that advised for Potatos. Cover the seeds with the finer particles of the soil to the depth of 1 inch. Water them well, and place the seed-boxes in a house having a temperature of 50°. Select dwarf-growing sorts for this sowing, in order that they may be planted out in frames eventually. Pioneer, Prince Arthur, and Chelsea Gem are suitable varieties.

Broad Beans.—It is a great advantage to raise Broad Beans in boxes, particularly where the soil is of a cold, heavy nature. The treatment should be the same as that recommended for Peas.

General Remarks.—To maintain a constant supply of salads place Chicory and Dandelion roots in a warm, dark place at intervals of twelve days for forcing. Sow Mustard and Cress in boxes in gentle warmth. Endive is more nutty in flavour if blanched in a low temperature, a cold, frost-proof frame for preference. The frame should be well matted or covered with dry litter, to exclude the light and frost. Rhubarb may be treated as advised for Seakale. Have under cover the various soils for making composts, as many seeds will require to be sown from the end of the present month onwards. Procure protecting material, such as long litter, Bracken Fern, Fir, or Yew boughs as a protection against cold, cutting winds. Sprout early Potatos in boxes.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Coelogyne Mooreana.—This species is by no means common, though it has been some years in cultivation. The usual season of flowering is from mid-autumn till the present time; the erect flower-spikes are very attractive. When in good condition the plant grows and flowers freely, but it is apt to be attacked by insects, especially red spider, when grown in an over-heated or dry atmosphere. It flourishes on the stage in a house having an intermediate temperature. A free supply of moisture at the roots is necessary during the growing season. The compost may consist of two-thirds Al or Osmunda-fibre and one third Sphagnum-moss. Pots are the best receptacles, and they should be well drained. The young growths, from the centre of which the bloom-spikes have been produced, are sending forth new roots, and the present is the most suitable time to repot any plants that may require fresh rooting material, provided the flower-spikes have been first removed.

Coelogyne barbata.—This is another highly desirable species of Coelogyne suitable for growing in an intermediate house. Its cultural requirements are similar to those of C. Mooreana, except that it should be grown suspended near the roof-glass in a light, airy position to ensure a solid growth; if carefully treated as autumn approaches the plant will flower freely. Guard against over-potting, as the plants give much more satisfactory results when the roots are in a restricted space.

Vanda Amesiana.—The erect racemose spikes of fragrant flowers produced by this distinct winter-blooming Orchid are very beautiful. In its thickened cylindrical leaves the plant is like a stout form of Vanda Kimballiana, to which pretty species it is closely allied. The plant will generally be satisfactory in a house having an intermediate temperature, and it should be grown in small baskets suspended from the roof. At Westonbirt it is exposed to all the sunlight possible, and plenty of fresh air, this treatment producing solid, free-flowering specimens. The species is a mountain plant, and cannot thrive in a close, badly ventilated house, or one in which the air is not constantly changed. In their natural habitat the plants are said to shrivel considerably during their dormant period, but it is not advisable to go to such extremes under cultivation. Such treatment—by many miscalled rest—is very weakening and harmful to the plants and unnecessary.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Propagation of Figs.—The present is a suitable time to prepare a new stock of Figs. Shoots of last year's growth should be cut into lengths, retaining one eye on each; these may be inserted singly in small pots, or several may be put in larger pots, placing them just below the surface of the soil; plunge the pots in a steady bottom heat of 70° to 75°, and do not keep the soil excessively moist until growth commences.

Tomatos.—Make a sowing now to provide a succession to the plants raised during November or early part of December. Sow the seeds thinly to ensure sturdy specimens; place the pots, pans or boxes in a propagating case and cover them with a sheet of glass or brown paper. After germination has taken place, admit air to the plants gradually, and expose them fully to the light. To encourage sturdy growth a night temperature of 55°, with a moderate rise by day, will suffice, and air should be admitted when the weather conditions are suitable, but cold draughts must be prevented. Plants raised from an early sowing will soon have filled their pots with roots, and should then be shifted on, either into 6-inch pots or into their fruiting pots, according to requirements. The soil for the final potting should consist of three parts good fibrous loam and one part well decayed leaf-soil, with a little wood ash and coarse sand added. Nine-inch pots, well drained, will be large enough for this batch to fruit in. Pot firmly, and supply water in moderation until the plants are well rooted.

Early Vines.—Early vines are in various stages of growth, and the different operations will demand prompt attention at the proper time. Daily attention will be necessary in disbudding and tying the shoots when growth is sufficiently advanced: each shoot should be "stopped" at the second or third leaf beyond the bunch, according to the space available. When all the buds have started into growth syringing should be discontinued, but the borders, walls and paths should be slightly damped two or three times a day, according to the state of the weather. An excess of atmospheric moisture should at all times be prevented, as it tends to promote long-jointed shoots and thin, flimsy foliage. When growth is free, afford a night temperature of about 60° with a rise to 70° or 75° by day, and an additional 5° to 10° when the house is closed. As at this period the foliage is soft and tender, air must be admitted cautiously, and the amount admitted must be governed by the prevailing condition of the weather.

PLANTS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

Hippeastrums (Amaryllis).—The numerous varieties of florists' Hippeastrums form a most useful class of decorative plants for flowering in late spring. After a period of rest the bulbs should now be examined, and the largest and best-rooted specimens selected for early forcing. The soil about each bulb, being quite dry, should be thoroughly watered, adding to the water a little liquid manure. When the excess of water has drained away remove the soil, taking care not to injure the surface roots, and top-dress the plants with good loam mixed with concentrated fertiliser. The most successful way to grow Hippeastrums is to plunge the pots to their rims in a bed affording a mild bottom heat. The atmospheric temperature should be 55°. Syringe the plants daily, and keep a close watch for insect pests. The pots, being plunged in moist material, very little water will be needed until the plants have made considerable growth, when they may be given frequent waterings, enriched with a little concentrated fertiliser.

The Forcing of Flowering Plants.—In present circumstances many will be tempted to commence the forcing of flowering plants in warm fruit houses, but this should be discouraged, because of the danger of introducing insect pests into the fruit houses. In a special plant-forcing house it is not necessary to provide a high temperature; if the house contains a pit with bottom heat it will be an advantage. Azalea Deutsche Perle and other early-flowering varieties grown in a house having a temperature of 55° and syringed daily will soon come into flower, and may then be removed to cooler quarters.

Spring Flowers.—Bulbs of Daffodils that have been previously plunged in a bed of ashes in a cold frame may be introduced into a glass-house in batches as required. Force them slowly on a mild bottom heat and remove them to the flowering houses later. Early double Tulip Murillo may be treated in the same manner. Freesia refracta alba that were potted 4 or 5 bulbs in each pot last August, and grown under cool treatment, will now be flowering. Early-flowering Rhododendrons, Azalea mollis, Lilacs and Viburnums are all suited for early forcing without much warmth. Plants of Calla aethiopica, when in full growth, and showing flower-spikes, should be well watered with liquid manure. The leaves and flower-spikes of the common Arum are subject to attacks of green fly and should be sponged or syringed with an insecticide.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Gooseberries.—These useful bush fruits may now be pruned, but where the work can be left until March it is advisable to leave it, because when pruned early, and hard weather follows pruning, birds are very apt to ruin the prospects of a crop by picking out the buds. Care and intelligence are required in pruning fully-grown bushes; if pruned too little a thicket of weak growths and small fruits result; on the contrary, if pruned too severely strong growths and a small quantity of large fruits follow. The aim should be to secure a well-balanced bush by thinning out old wood and leaving as much young wood as will furnish the bush without overcrowding. It is a good plan to leave the top shoots rather long for the time being, as I find that when birds are hungry they generally settle on and pick the buds out of the uppermost shoots. All weakly growths should be cut close in. To defeat the birds it is a good plan to string black thread across the bushes in various directions. Dusting the bushes occasionally with lime acts as a preventive against caterpillars if used as soon as slaked. Where caterpillars were troublesome last summer it is advisable to remove about 2 inches of the loose soil from underneath the bushes, dust the surface with fresh lime, and apply good compost in place of the soil removed. The ground around and under the bushes should be mulched with manure, as recommended for Currants, as this encourages clean growth and good crops, and reduces their liability to the attacks of many pests. All the ground in a Gooseberry plantation should be lightly turned over when the weather is favourable, taking care not to damage the roots when forking close up to the bushes.

Planting.—Gooseberries may be planted now, and as they are very accommodating they will succeed in nearly any position, provided they have a good depth of soil to root in. Light, gravelly soil does not suit Gooseberries, and where planting has to be done in such a medium good turfy loam should be provided for each bush.

Cuttings.—Gooseberry cuttings may still be inserted. Select well-ripened growths of last season, about 1 foot long, and remove all the eyes on the bottom half. Insert the cuttings firmly about 6 inches apart and 4 inches deep, and allow a space of 1 foot between the rows.

Grease-Bands on Fruit Trees.—A close watch should be kept on grease-bands on Apple trees, and where necessary the sticky material should be renewed, to prevent the female moths from ascending the trunks, as they are very active now.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Violas.—Violas propagated from cuttings inserted in beds in the open should be weeded carefully, and if the plants have been loosened in the soil through the action of frost, press them firmly round and about the roots. Dust the foliage occasionally with soot to prevent damage by slugs.

Flowering Shrubs.—When the weather is suitable proceed with the planting of flowering shrubs. The stations for single specimens should be carefully prepared by breaking up the soil to a good depth, ensuring ample drainage, and providing a suitable compost to give the plants a good start. Naturally, equally good preparation is desirable where beds or groups are to be planted. Some soils and situations are naturally well drained, and in such cases comparatively little preparation is needed. In heavy, clayey land some of the natural soil should be removed and soil imported suitable to the growth of the particular kind of shrub. Magnolia Soulangeana, M. grandiflora, M. stellata, Pyrus Malus angustifolia, P. M. floribunda, P. M. atrosanguinea, Weigelas, double-flowered Cherries and Thorns are a few of the most desirable flowering shrubs.

Pruning and Mulching Shrubs.—Most flowering shrubs require a little timely pruning either to restrict growth or to encourage a pleasing habit, therefore these matters should be kept in view from the time the shrubs are planted. Place a mulch of leaf-mould or decayed manure over the root-area of all newly planted shrubs. Stake standard specimens and protect them from injury by rabbits. See that each plant is correctly labelled, and examine the fastening of all suspended labels on trees previously planted and replace any ties that are too tight.

Sweet Peas.—Sweet Peas should be sown in pots and forwarded under glass to supply early blooms. The main point to be observed in growing these plants under glass is to keep them as sturdy as possible until they are ready to plant out in the open. A large number of varieties is not essential for cut purposes only. I usually depend on one good variety each of white, pink, mauve, and crimson selfs. Select clean, dry pots; use ample drainage material, and fill with a good compost. Sow the seeds more thickly than for later batches; be careful not to over-water the soil.

Chrysanthemums.—Should it be desired to increase the stock of early-flowering Chrysanthemums, and roots have not been potted for the purpose, a few stools should be lifted and placed in gentle warmth, where they will soon provide a supply of shoots suitable for cuttings, many of which may be separated from the stool with roots attached and potted in small pots. With reasonable attention these will make fine plants for subsequent planting on good land, where they will grow rapidly.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* Publisher; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* Editors. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.6°.

Actual Temperature:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, January 22, 10 a.m.: Bar 30.25; temp. 41°. Weather—Dull.

Food Statistics in Relation to the War. The reference handbook* on this subject prepared by Raymond Pearl and Esther Pearl Matchett on behalf of the Statistical Division of the U.S. Food Administration, contains information of absorbing interest and permanent value. Who among the Allies, for example, would have guessed that the allied nations contained a population eight times as numerous as that of the Central Powers? How could the ravages and disorganisation brought about by war be more strikingly illustrated than by the fact that, although the European Allies—and the Central Powers, too—have to look to America for food supplies, yet the total area normally under cultivation by what may be called the European Allies is three times that under cultivation by the group of "American Allies," which, for the purposes of this computation, includes not only the United States, but also Canada? It is not reassuring either to discover that whereas the percentage of total population engaged in agriculture is in France 22, and in Germany 15.6, it is only 4.9 in the United Kingdom. Yet there is a brighter side, for in Wheat production as increased in yield per acre, the United Kingdom, with an average of thirty-three bushels, beats Germany with thirty, and France with nineteen, the United States with seventeen, and Austria-Hungary with fifteen, although we are beaten in turn by Belgium with thirty-five, Holland with thirty-nine, and Denmark—which heads the list — with forty-three bushels per acre. (Three years' pre-war averages.) Again, during the war (1915-1916) our Wheat area was increased by 455,000 acres (from 1,880,000 pre-war to 2,335,000 in 1915 and 1916), whereas that of France fell from 16,347,000 pre-war average to 13,564,000 in 1915 and 1916; and that of Germany in the same time only showed an increase of 96,000 acres. The statistics relating to the large increase in this country in 1917 and 1918, which was brought about as a result of the active campaign carried on by the Food Production Department of the Board of Agriculture, were not available when the *Reference Handbook* was compiled.

The facts concerning Potato production are also worthy of note. Germany, as is well known, produced an extraordinarily large quantity of Potatos, which in the three pre-war years amounted on the average to 41,000,000 tons; but the German yield (in Winchester bushels = 54.2lbs. per acre) was only 204, as against 220 in the United Kingdom. These yields are, however, far surpassed by those of Denmark, 237 bushels; Belgium, 291 bushels = 7 tons; and Holland, 305 bushels = nearly 7½ tons.

Although Germany made a great effort in 1915, and produced an additional quantity amounting to nearly 6,000,000 tons, she was not able even to maintain her pre-war production in subsequent years. Thus in 1916, from an unascertained acreage, German Potato production only was less than half that of the pre-war average, namely, about 19,000,000 tons. Thus the prediction made in this journal that pig and Potato production would be decisive factors in the war appears to receive signal justification—at all events, with respect to the Potato.

The statistical part of the *Reference Handbook* is supplemented by a valuable series of tables of conversion units, grain and other crop measures, and American equivalents of measures and weights in use in other parts of the world. In view of the importance at the present time of full statistical information in a readily available form, we are of opinion that this useful compilation should be made generally available in this country. We could, however, have wished that some of the more important fruits had been included in it.

* *Reference Handbook of Food Statistics in Relation to the War.*

Royal Society of Arts' Lecture. — At the meeting of the Royal Society of Arts on Wednesday, the 29th inst., a paper on "Food Production by Intensive Cultivation" will be read by Dr. Frederick Keeble, F.R.S., Controller of Horticulture, Food Production Department, Board of Agriculture and Fisheries. The chair will be taken at 4.30 p.m. by the Right Hon. Lord Lambourne, C.V.O.

Chelsea Show, 1919, and Wisley Gardens Endowment Fund.—Since the Fellows' tickets for 1919 and the Annual Report for 1918 were printed, the prospect has become much more promising for the supply of tenting for the usual great meeting of the Royal Horticultural Society held at Chelsea which, owing to war conditions, had to be abandoned in the years 1917 and 1918 so much so that the Rev. W. Wilks now states, on behalf of the R.H.S. Council, that a meeting will probably be held at Chelsea on May 20, 21, 22. Growers—both amateur and trade—have been approached, and have made a most favourable response, and in all cases they promise to send abundant specimens illustrative of the latest advances made in horticulture. The Council proposes to hold this meeting in aid of the Society's Wisley Gardens Endowment Trust Fund and the important practical and scientific work it was set up to accomplish. This Fund was established in 1914 by a Deed of Declaration of Trust, and falls within the definition of "a charitable or philanthropic purpose."

V.M.H. for Sir Frank Crisp. — Only one vacancy occurred during 1918 in the Roll of the Victoria Medal of Honour in Horticulture, and to fill this the Council of the Royal Horticultural Society has appointed Sir Frank Crisp, who has done much good work for horticulture, especially in connection with alpine and rock plants, and as president of the Horticultural Club.

M. Albert Maumené. — Monsieur Albert Maumené, the well-known French horticultural journalist and editor, writes us as follows: "Some English gardeners on the Côte d'Azur have told me that you published in the *Gardeners' Chronicle* some time ago a note to the effect that you were without news of me. After the mobilisation I was at the Front until the end of April, 1918, and then I was recalled by the Minister of Agriculture for the organisation of the work of restoring the ruined farms in the north of France. I am now preparing to issue once more my publications *La Vie à la Campagne*, *Jardins et Basses Cours*, and *Agriculture Elevage*, which have been suspended during the war. I am very grateful to you for your kind remembrance of me."

Edward Mawley Memorial. — In 1917 the National Rose Society raised a special fund in order to provide some suitable memorial to the late Mr. Edward Mawley, who for 37 years was hon. secretary of the Society, and who died during his presidency. A sum of nearly £180 was subscribed, and this has been applied (1) to the erection of a memorial window in St. Michael's Church, Berkhamsted, and (2) to the striking of a medal, which will be known as the Edward Mawley Memorial Medal. The window was dedicated on December 4, and a description of it will appear in the N.R.S. Rose Annual. Two Edward Mawley Memorial Medals will be awarded, for the first time, at the summer show on July 2, 1919.

Revision of Pritzel's "Icones Botanicarum Index Locupletissimus."—The Royal Horticultural Society has already commenced the revision of "Pritzel," and the work is being carried out with the assistance of botanists attached to the Royal Gardens, Kew, the Natural History Museum, and the Linnean Society, and in friendly co-operation with the United States Government Plant Bureau, but the financial responsibility rests with the R.H.S. The original *Icones Botanicarum*, compiled by Dr. G. A. Pritzel, was published in 1866, and is a dictionary of published illustrations of every plant then known, and it contains over 100,000 references and figures, the book and page being given in each case. Such a work was and is invaluable to those engaged in botanical or horticultural research, but as the last fifty years have been more productive of new plants discovered than any previous half-century, the necessity for revision and enlargement has been obvious for a long time past, and would have been carried out earlier had not war imposed a check. It is estimated that the new work will include about 250,000 references and cost at least £3,500, possibly £4,000. Towards this cost the R.H.S. has voted £500 and the Veitch Memorial Trustees £100. The fund was started with £250 from the International Horticultural Exhibition held in 1912. Subscriptions are invited. The names of those subscribing £1 1s. will be published in the new work; every subscriber of £15 or upwards will receive a presentation copy; a subscriber of £50 will receive a copy bound in half-calf; and a subscriber of £100 will receive a copy bound in calf or vellum. The revision is being done at Kew, where the Director has found accommodation for the typists, who are preparing the manuscript under the personal supervision of Capt. Arthur W. Hill, the Assistant Director. The members of the Pritzel Revision Committee are: Prof. I. Bayley Balfour, Mr. E. A. Bowles, Mr. F. J. Hanbury, Capt. Arthur W. Hill, Dr. B. Daydon Jackson, Mr. Gerald W. E. Loder, Sir Daniel Morris, Sir David Prain, Dr. A. B. Rendle, Dr. O. Stapf, and Sir Harry J. Veitch.

Ripley Castle.—The death of Sir William Ingilby, of Ripley Castle, Yorkshire, recalls an interesting fact connected with the beautiful gardens attached to the Castle, for, according to *Truth*, Eugene Aram was the son of a head gardener at Ripley Castle, and some of his letters are preserved in the library. It would be interesting to know whether Mr. Aram, senr., was

NOW IS THE TIME TO PLANT PAEONIES

The War is over and we have kept our stock intact, although many other plants have ceased to exist in our Nurseries owing to the withdrawal of labour. There is no plant so satisfactory as the PAEONY to plant for permanence in a garden. It is essentially perennial and hard to kill by neglect.

The plants we are now offering, owing to the War, are larger than usual and full of bud, and planted now should be in good flowering state next year and for many years to come.

We offer Collections, chiefly English varieties raised in our Nurseries, and comprising all the various colours, strong as well as delicate, for which the Paeony is celebrated.

COLLECTIONS OF KELWAY'S LOVELY HERBACEOUS PAEONIES.

Named Varieties, as advertised, the selection of sorts being left to Kelway and Son.

COLLECTION "C," 36/- per dozen, 3/- per plant net, more recent kinds and the best of the older varieties, and fragrant sorts.

COLLECTION "D," 54/- per dozen, 5/- per plant net, more recent kinds in the most delicate tints and most fragrant sorts.

COLLECTION "E," 70/- per dozen, 6/- per plant net, very recent novelties of finest form and most enchanting colours and fragrance.

COLLECTION "F," 90/- per dozen, 7/6 per plant net, Cream of the collection.

CHRYSANTHEMUMS

The celebrations of the Anniversary of Armistice Day, November 11, will in future years cause a bigger demand for flowers than has previously been experienced.

The Chrysanthemum will be the leading feature for supplying the demand, and will be at their best at that time.

We have Large Stocks of the very best sorts for all purposes. Write for our List or advice, or let us know your requirements. Plants in February or March, suitable for this or any other period of flowering, **5s.** per dozen, or **30s.** per **100**, our selection.

Our stocks of the leading Japanese, Incurved, Decorative, Single and Early-flowering varieties are well up to our usual standard, but in view of the enormous demand orders should be given now.

We are also able to supply, from March, the best varieties of Perpetual Carnations in thumb pots, at **15s.** per dozen, **£5** per **100.**

Sold by Nurserymen and Seedsmen everywhere.

a noted gardener in his day. The INGILBYS have been seated at Ripley since the reign of EDWARD III., and the family has received three baronetcies. The castle was rebuilt in the reign of MARY and PHILIP, and CROMWELL stayed there before the battle of Marston Moor.

Carnation Conference.—The British Carnation Society will hold a conference on Carnations on Tuesday, the 28th inst., at 7 p.m., at the Offices of the British Florists' Federation, 35, Wellington Street, Covent Garden. The conference will be opened by Mr. W. E. WALLACE, Eaton Bray, with "A Chat about Carnations."

Scottish Potato Show in Edinburgh.—At the recent annual meeting of the Scottish Horticultural Association, Mr. ROBERT FIFE announced that the Scottish National Potato Exhibition would be held in the Waverley Market, Edinburgh, on October 29 and 30, 1919.

News from Belgium.—Monsieur A. DE SMET, the well-known nurseryman, of Laerne, near Ghent, Belgium, writes us as follows:—"I am very glad to have the opportunity of writing to English nurserymen once more. I cannot adequately express my gratitude to the British people for the helping hands they have held out to the Belgians. I did not escape the common fate of Belgian nurserymen during the war—my nursery grounds and all the glasshouses are completely destroyed."

Primula warleyensis (see fig. 15). — This charming Primula was given the R.H.S. Award of Merit when shown by Miss WILLMOTT at the meeting of the Royal Horticultural Society on March 26, 1912. It was raised at Warley Place from seeds collected by Wilson in Western China, and the illustration here given was prepared from a photograph taken in those well-known gardens. It belongs to the smaller section of the genus, and forms tufts of small, oval leaves on comparatively long, slender petioles. The leaves are green above and slightly farinose beneath, with serrated margins. The mauve-coloured flowers, about three-quarters of an inch in diameter, are produced in umbels of two or three together on stems about 2 inches high. It is a charming little plant, but, like most Primulas, requires to be periodically raised from seeds. These are produced freely when the flowers are hand pollinated. Specimens in the open require a somewhat dry, shady ledge, but it is more suited for culture in pans in a cold frame.

A Record in Visiting.—For a period of sixty years Mr. JAMES GRIEVE, of Redbraes Nursery, has made it a practice of taking a walk in the Royal Botanic Gardens, Edinburgh, on New Year's Day. From 1859, the first occasion of his visits, till this present year, he has never once missed paying his accustomed call. At the time of his first visit he was employed at the nurseries of Messrs. DICKSON AND CO., and he recalls how on that and many successive calls permission had to be obtained before a visitor was allowed to enter. The father of the present Regius Keeper, Professor J. H. BALFOUR, occupied that position in 1859, and Mr. JAMES McNAB was the principal gardener. Naturally Mr. GRIEVE has seen many changes in the personnel of the officials and staff of the garden, has many reminiscences to tell of his visits, and has seen the introduction to the garden of many of the trees and shrubs now growing there. His many friends will be pleased to know that he is still hale and hearty, and it is to be hoped he may add many more to the number of his annual visits.

The Status of Gardeners.—The Gardeners' Club for Women at Bristol has had under consideration a proposal to form itself into a local branch of the British Gardeners' Association. In furtherance of this movement, a meeting was held at the University a few days ago, at which Mr. CYRIL HARDING, secretary of the B.G.A., gave an interesting lecture, in which he is reported to have said that legally gardeners had no position of their own, and for all purposes of giving and receiving notice they ranked as domestic servants. But under this rank a gardener does not benefit when an employer left a legacy unreservedly to his domestic servants unless he was (a) living in the house of his employer, or (b) working for part of his time in the house. Mr. HARDING quoted Prof. ASHLEY to the effect that a gardener is incoherent. That does not mean he is speechless or incapable of expressing his views, but it means that, generally speaking, gardeners are isolated, with no means of getting together and discussing their position. That difficulty, said Mr. HARDING, was being overcome by the B.G.A., which is now a registered trade union for all horticultural workers over 16 years of age, and has for its main objects the organisation of all horticultural workers over 16 years of age, and tions of labour, working hours and wages, and the settlement of disputes between members and their employers. Mr. HARDING expressed the view that as a result of their efforts in food production, and the demand for open spaces, allotments, and town-planning schemes, the position of men and women gardeners would be greatly improved in the near future.

FIG. 15.—PRIMULA WARLEYENSIS: FLOWERS MAUVE-COLOURED.

Minimum Wages for Gardeners and Estate Employees.—Interesting notes on minimum rates of wages are given from time to time in the *Wages Board Gazette*, the official organ of the Agricultural Wages Board, and in the issue for January 15 it is stated that questions are frequently raised in correspondence, and also in the course of the work of enforcement by the Inspectors, as to whether the work in which a particular worker or class of workers is engaged comes under the minimum rates of wages fixed by the Wages Board. The Wages Board has no authority to give legally binding decisions in regard to such questions, which involve the legal construction of terms used in the Corn Production Act and in the Board's Orders, and which could, therefore, only be authoritatively settled by a Court of Law. Nevertheless, the Board has felt it desirable to give assistance in these matters, and has expressed opinions on individual cases, on the clear understanding that an expression of opinion is without legally binding force. The term "agriculture" includes the use of land as market gardens and nursery grounds, and workers employed in estate or private gardens would, in the Board's view, come within the scope of the minimum rates if the produce was grown wholly or partly for sale. The Board is inclined to the opinion that workers in estate or private gardens would not come within the scope of the minimum rates if the produce was grown solely for the occupier's private use. The term "agriculture" includes the use of land as woodland, and all workers employed in woodlands, including estate woodmen, would accordingly come within the scope of the rates, irrespective of whether the produce was sold or not. The following opinions have been expressed by the Board in regard to specific questions which have been raised: I. That the minimum rates would *not* apply to (a) Gamekeepers; (b) men employed as vermin killers and rabbit catchers; (c) clerk working in the office of a home farm; (d) estate sawmill engine driver; (e) estate sawmill labourer; (f) the office staff of a firm of nurserymen and seedsmen; and (g) private and estate gardeners, provided the produce is grown solely for the occupier's personal use. II. That the minimum rates *would* apply to (a) men in charge of herd of breeding pigs; (b) workers employed on a poultry or egg farm; (c) grooms employed by stallion owners to look after stallions; (d) apprentices under indentures to a firm of nurserymen; (e) the carter to a market gardener employed in carting the produce to market; (f) men employed in private or estate gardens, the produce of which is grown wholly or partly for sale; and (g) a man employed at a private sanatorium as a gardener for food production. III. As regards estate workers, such as carpenters, masons, drainers, plumbers, bricklayers, the opinion expressed is that if the principal and usual occupation of the worker was that of a carpenter, or mason, or drainer, or plumber, or bricklayer, the mere fact that the work of carpentering, draining, etc., was in connection with agriculture would not in itself bring the work within the scope of the minimum rates, but if the principal and usual occupation was that of an agricultural worker, the worker should be paid at not less than the minimum rates in respect of the whole period of his employment, notwithstanding that he might be engaged from time to time in work which in itself would not be regarded as an agricultural operation.

Publications Received.—United States Department of Agriculture Bulletins. (Washington: Government Printing Office): No. 721, ***The Beet-Sugar Industry in the United States.*** By C. O. Townsend.

HOME FOOD PRODUCTION.

On November 16, at Central Hall, Westminster, Mr. Lloyd George said: "In 1913 300 millions' worth of the products of the soil were imported from abroad which could have been produced here, and could have employed 400,000 more workers in the healthiest of occupations. That is one of the problems, and I trust that a good many of the soldiers, when they come back, will be settled on the soil."

The armistice recently concluded leaves the British people with two very serious problems to face, one being the necessity for completing, in conjunction with our glorious Allies, a permanent peace; the second, the reconstruction of practically everything concerning our daily life from an industrial point of view, and one of the biggest factors of this latter question is undoubtedly the provision of our daily food.

Whilst it appears to me that the Prime Minister's figures of value quoted above are possibly very liberal, yet the fact remains that for years past vast quantities of foodstuffs have been imported from abroad which could and should have been produced in this country. When one considers the following figures for food imports alone in 1913 (the last normal year prior to the outbreak of war) one is almost staggered to see what a chance to "colonise" Britain has been wantonly thrust on one side:—

IMPORTS OF FOODSTUFFS, 1913.

	Approx.
Grain and flour	£85,500,000
Meat	57,000,000
Butter, eggs and cheese	40,500,000
Lard	5,000,000
Fruit	12,500,000
Vegetables	6,000,000
Sugar	23,000,000
Approx.	£230,000,000

Had proper steps been taken—and the neglect nearly cost us dearly during the war—what a large portion of this enormous food bill could have represented home production instead of imports, with the resulting increase of healthy employment available. I should think, for more than Mr. Lloyd George's 400,000 workers, especially when one considers that in the same year, it has since been estimated, there were no fewer than 17 million acres of land not properly utilised in the British Isles, by far the greater part of which could have been employed most usefully.

A few, including myself, had repeatedly urged for many years prior to 1914 that steps should be taken to ensure a greater measure of self-support. We frequently advocated that more land should be put under cultivation, but our appeal met with no response, yet when war broke out everyone was eager to "get back to the land," and a great demand arose for plots and allotments, with what splendid results we all know. We old prophets, as we had been looked on, saw accomplished to a certain extent within a couple of years what we had done our best to force home for one, two, and even three score years. All credit to these amateur cultivators, for they all did marvellous work within a short time. The triumph of November 11 was a dual one of spade and rifle, for victory was won not only abroad by the army and navy, but also by the humble tiller of the soil at home.

Napoleon, Emperor of France, referred to the British people as a "Nation of Shopkeepers," but the shopkeepers defeated the aims of the tyrant. To-day, the imitation Napoleon, Wilhelm, ex-King of Prussia, has been overthrown largely by the help of a nation of whom a large number are allotment holders. As we maintain our trading tradition, so must we foster our new spirit, and no effort should be spared by the authorities to keep the allotment cult thriving, and extend not only the numbers that do the work, but also to use every means of affording facilities for food production, as well as enlarging its scope. The London and Southern Sections of the National Union of Allotment Holders, the delegates of which recently met in London, comprise about 52,000 holders; the aim should be a membership of 520,000, and even more.

When the first steps were taken to cultivate land and grow more food in this country, many things were done heedlessly, and playing-fields, lawns, public parks, and recreation grounds were put under the spade. Such errors should now be remedied so far as is possible, for there was, and is, plenty of open ground that could be used without encroaching on land that is already serving a useful purpose. I would be the last person to suggest that allotments, which were formed as the result of misapplied enthusiasm, should be maintained where other land can be provided. But the majority of plots, including those on waste spaces and vacant building land, should certainly be retained, as we shall need all the food we can raise for some years to come. The tenants of such plots must be assured of a security of tenure, and every assistance should be afforded them by the authorities.

New ground must be made available, and not only for allotments, but also for small holdings, for in a real effort to colonise England small holdings will be unquestionably in great demand. There are thousands of acres of land lying practically idle which, with a proper system of cultivation, could be made to grow good and profitable crops, and over and above these efforts there is the need of afforestation. Much land, so often referred to as useless, can be made to pay when properly treated and worked, and every effort and assistance must be directed to such an end, and especially in the conversion of poor pasture and bad grass land to productive arable land.

One often hears people remark that many of the brave lads who have faced fearful perils for us in the war will eventually drift out to the Colonies, but the question arises whether it is necessary for all, or even a great number of ex-soldiers, who desire work in the open, to emigrate. My answer is that it is not necessary, provided our Government will tackle the task bravely, and afford these men, who are the very healthiest of our race, the chance to work on the land, with the added incentive and inducement of becoming their own masters. No finer work could be found for the ex-soldier than the raising of food in his native land, and the chance must be afforded him, either in agriculture or horticulture, of raising some of the six million pounds' worth of vegetables and the 85½ million pounds' worth of grain, to say nothing of the other produce previously imported from abroad.

Where, again, could a finer means of employment be found for men partly incapacitated, or invalided out of the army and navy, than in growing fruit, for much of the 12½ million pounds' worth of imported fruit could be grown at home, and the work would not prove either heavy or tedious labour, but would ideally suit many of these brave but handicapped men. There is therefore no reason why small colonies of partially disabled men should not be established up and down the country for the special purpose of fruit-growing.

The positions of no fewer than fourteen millions of our workers will be reshuffled in the work of reconstruction after peace is proclaimed, and many thousands of them could find new employment on the land.

At Aldershot and other large camps soldiers have converted many acres of barren, idle land into plots that have proved very productive indeed, and ground has been similarly utilised in France and elsewhere. This is sufficient proof of the ability of the soldier as a food producer. Some camps were less good than others, but I fancy this can be traced to the moving of units from one place to another, for the work on the whole was exceptionally good.

There is a grim phrase in the Prime Minister's speech (an extract from which appears above), wherein he says: "The wealthiest country in the world. Hundreds of thousands of people in it broken physically because they were underfed, ill-housed, overworked, perhaps many poisoned with excessive alcohol drinking, to which they were driven by squalor." Not only squalor accounts for one of the evils mentioned, but also lack of any interesting occupation for spare hours. What is a more healthy, interesting, and profitable recreation for a man than to cultivate an allotment for a short while after a day's toil at some other occupation? And yet there are many villages, not to mention towns, where facilities for allotments do not exist in anything like a sufficiency, and where as a rule the house gardens only comprise a few yards of hopeless soil. More and more ground is wanted for the small grower, and above all near to his home, not miles away, where he can only visit his plot for, say, about a couple of hours a week. The plot should be close at hand, so that he can get to it during the light evenings. In any system of town planning there should be powers to enforce these necessary adjuncts to dwellings, and the latter also must be improved. The social side of life must be made more attractive in the villages than it is at the present time, for it cannot be expected that large numbers of the dwellers of cities and towns, where everything is bright and interesting, and where the facilities for pastimes are innumerable, will settle on the land if they are faced with the prospect of living a dull, drab, monotonous life in a country hamlet.

THE ECONOMIC ASPECT.—There is a vast range in the economic questions affecting land work, and especially with regard to small holdings, but the three principal items are, I consider, transport facilities, market arrangements, and financial security.

Transport.—The question of transport is one of the most serious problems that the Government has to solve, and it particularly affects the question of home production. High rates of freight and delays and difficulties appertaining to transport have done more to destroy the small farms of Britain than foreign competition or any other cause, and must be radically remedied without delay if small holdings are to prove successful. Canals and railways linking up the country districts with the big industrial centres are more urgently needed than ever, so that home produce can be placed cheaply and quickly on the markets whilst ensuring a proper profit for the producer.

Market Arrangements come second in importance from the point of view of the small grower. It is useless for the little man to produce in small quantities if his goods cannot reach a market, for though, as runs the Scotch proverb, "Mony a mickle makes a muckle," one has to get the "mickles" together before the "muckle" is realised. For this purpose I would advocate that the local War Agricultural Committees and Food Control Committees appointed some time since should be retained, and be the authorities to whom are allotted powers to arrange the collection of small lots of produce in their particular districts, and the eventual disposing of the same to markets, etc., so that the "mickles" may thus reach the consumer and not be left on the producers' hands to waste.

I had the oppor' inity, whilst on a holiday at Bournemouth last ear, of witnessing a co-operative market system that had been established there, whereat small lots of vegetables, fruit, eggs, butter, poultry, and other produce were put up for sale by auction, and it was surprising what a demand existed, and what good prices were realised. Here, then, is the nucleus of a system that could with advantage be extended all over the country.

Finance is another matter that will require very careful consideration by the Government and will be necessary in the form of Land Banks, or other means, to give the necessary financial backing required by small farmers, etc., to

enable the go-ahead men to make a real success of their efforts. Money will be one of their greatest needs, coupled with the opportunity to get land for their purpose, and means to obtain necessary mechanical aid, seeds, fertilisers, etc., at reasonable rates. If this matter is boldly yet cautiously handled there is but little doubt that great success will result not only for the individual, but also for the nation.

Afforestation.—There is little land in this country that is not capable of producing some commodity or other, and where it is unsuitable for growing vegetables, fruit, corn, etc., and is useless for grazing, it could be devoted to afforestation. Nearly thirty-four million pounds' worth of wood and timber were imported in the year 1913, besides $3\frac{1}{2}$ million pounds' value of manufactured wood and timber. The growing of timber would provide work for further labour, and the poorest land could be utilised for the planting of forests. Afforestation is a subject of great urgency, especially in view of the world shortage of timber and the large quantities that will be required for rebuilding the ruined places of Belgium, Northern France, Serbia, and other countries which the enemy has burned and destroyed.

I have written these remarks with the hope that they will give a lead to thinking men and women who, when they realise the urgency of the subject, may cause our administrators to understand the real necessity of not only maintaining the food production work on the land broken up during the past few years, but also the imperative need of giving increasing and practical aid to the important industries concerned, in order that we may become far more self-supporting as a nation, and, besides providing healthy work for our big population, never again risk finding ourselves so near starvation as we were in 1917. In furtherance of this aim let me urge the need for more practical and interesting lectures on these matters for the information of the "man in the street," and even an extension of the system of school gardening whereby the children may receive, as part of their curriculum, a knowledge of the cultivation of the land, a knowledge that may serve them in such good stead in later life. *Edwin Beckett.*

MEDICINAL PLANTS.*

(*Continued from p. 22.*)

When speaking in Edinburgh in 1913, at the pharmaceutical conference, Sir Edward Evans, chairman of one of the largest manufacturing firms in the world, said: "I would like to point out that the soil of this country seems adaptable for this purpose (the growing of medicinal plants), as what it does produce is superior to any produced elsewhere." He then specified a series of plants for cultivation. Here we have the head of a huge business, with a thorough, practical and intimate knowledge of what is required, advocating the establishment of this rural industry. And this was before the war, which is a very important point to keep in mind, for his advocacy was based on the keen-cut pre-war prices produced by Continental competition, in spite of which he saw the value and importance of this work commercially. This powerful pre-war advocacy by Sir Edward Evans has been emphasised by Dr. Hooper, who for many years was superintendent of the botanical gardens and Government quinologist in India, and a practical botanist. When discussing the topic of home cultivation in an address given in London last July Dr. Hooper said that it was a matter of national importance, and that the imported German and Austrian drugs, though low in price, were inferior in quality to those grown in this country. Mr. Kilmer, an American, in reviewing the natural products of the world in an American journal, wrote that "Great Britain is an ideal land for drug culture, with a balmy, equitable climate, a varied and fertile soil, and a population of intelligent husbandmen. . . . If any one country might attain supremacy in drug culture it should be Great Britain." Quotations like these are somewhat on the lines of the proverb that "actions speak louder than words," and in connection with this the results obtained by the Evesham Small-Holders' Association are both practical and interesting. Apparently this is a group of smallholders who work co-operatively, and they have published their returns. They commenced working in 1915, and laid down 11 acres of Belladonna and $1\frac{1}{2}$ acre of Henbane. The combined expenses, including initial outlay, were £400. Their returns were, for Belladonna £1,300, Henbane £150—total, £1,450, for an outlay of £400. This is an excellent result for a trial run, especially when it is considered what an exceptionally poor growing season 1916 was. Judging from the Press reports which appear from time to time there is a residuum of people, who might be classed as "Doubting Thomases," who believe that when this great war is over the former state of affairs will be at once reverted to, and supplies again obtained from Germany. In fact some even advocate this policy, and consider drug cultivation as merely a temporary expedient to tide us over. Fortunately these timorous individuals are very few, and their opinions can only be considered as the outcome of a nervous or lethargic temperament, and a microscopic outlook on life. It is to be hoped that the future in store for this great nation will not tolerate the state of affairs which formerly existed, that home industries will be safeguarded by the Government, that Fair Trade will take the place of Free Trade, and that the small acreage of land under cultivation will become a thing of the past.

It has been said that it is no good attempting work of this kind in Scotland, but dogmatic assertions such as these seldom stand the strain of criticism. For an answer, reference must be made to Nature. Two of the drug plants most urgently required, viz., Belladonna and Henbane, are native to Scotland. In a field on the north side of Edinburgh Belladonna may be found growing in the hedge. Henbane is botanically abundant on the Berwickshire coast. Experimentally both these plants have been grown successfully and have a high standard of quality, answering all the tests of the *British Pharmacopoeia*. Is further evidence required? Like all problems of a horticultural nature, environment must be taken into consideration and carefully examined. In the pamphlet issued by the Board of Agriculture, and in articles in recently issued magazines and booklets, it is generally stated that Belladonna likes a chalky soil. This is true; but it does not of necessity follow that the converse is untrue. Belladonna is found growing in loamy and chalk-free soil, such as is found in the south-western counties and in the Lake District. It is also stated that Belladonna likes shade. This assertion must be accepted cautiously. It would be more accurate to say that Belladonna does not like a scorching sun, as prevails, say, on the Surrey hills. But such conditions do not prevail generally in Scotland, and in these northern districts an unshaded exposure will be found to be the most suitable.

The preparation of a herbal drug for the market is a matter of paramount importance, for a fine, well-grown specimen indifferently or badly preserved has little commercial value. Leaves and flowering tops must be collected in dry weather, and in the early part of the day. Great care must be exercised so as not to unduly break or crush them. If the collectors are given proper facilities, it is only a matter of skill and practice. Collection must be made by children if the work is to become commercially successful. They can soon be taught to do the work well under supervision, with proper encouragement. Roots must be washed. The easiest way is to dry them in the sun, when most of the adhering soil may be shaken off, after which they can be washed. The water adhering after the washing is merely superficial and readily dries off. Flowers are treated as leaves. The drying of leaves, flowering tops, flowers and roots is best done by means of air. Artificial heat is good, but demands close attention and great care and experience, for unless carefully managed the crops start to sweat, since more moisture is driven out than the air is capable of absorbing. This sweating destroys the colour of the leaves, and also the aroma. The process of drying by air is easily and simply accomplished by using an open-sided shed which admits a full current of air. Trellised racks are fixed to each side so as to be nearest the open air. Rough frames about 2 feet by 3 feet and 3 inches deep should be used, the bottom being covered with wire netting of about 2-inch mesh. These are placed on the racks, and about 12 inches of air space is allowed between each row. The crops are placed on the trays in thin layers, and turned over twice a day if possible until they are crisp. In undertaking a work like this it is necessary that all expenses should be reduced to the minimum. Ordinary unskilled labour must be employed whenever possible, and women and children must be used for the harvest work. Highly skilled horticultural labour must not be considered. Expense outlaid on the soil by the application of artificial manures is well warranted, as the crops are far more remunerative, and a greater amount of material is obtained from the same area of land and for the same amount of labour. Therefore an outlay in artificials is well justified, but in every other department look well to expenses.

A very important question is that of marketing the produce, and this must be carefully gone into. It is a very essential point, but one which it is somewhat outside the scope of this paper to deal with in detail. Broadly speaking, however, the best policy to pursue is not to depend upon the requirements of one or two direct users, like manufacturers. Distribution is best conducted through drug brokers, who handle raw drugs in enormous quantities, and upon whom the manufacturers largely depend for their supplies.

(*To be concluded.*)

HOME CORRESPONDENCE.

(*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*)

Seeds of Hippeastrum brachyandrum and Dierama pulcherrimum.—I shall be glad to send fresh seed of Hippeastrum brachyandrum and Dierama pulcherrimum to anyone who will send me a stamped and addressed envelope. *A. C. Bartholomew, 75, Tilehurst Road, Reading.*

"Blue" Orchids.—Mr. R. Windsor Rickards writes from Usk Priory, Mon., in reference to my article upon Blue Orchids, which appeared in your issue of January 4, p. 1, and sends me the interesting information that he saw in a garden in Rio in 1914 Acacallis (Aganisia) cyanea, which is very nearly pure blue in tone, and of great beauty. *Jeremiah Colman, Gatton Park, Surrey.*

Garden Tools.—A short while ago the ordinary English knife was criticised, and rightly, I think, by Mr. Brotherston (see p. 149, Vol. LXIV.), as an inefficient tool for cutting away things from the herbaceous border. The home product known as a garden or pruning knife is often a clumsy and inartistically made tool, and often, too, the steel or its temper deserves condemnation. The blade is too thick and the angle of set and curve are not good. Two hundred years ago J. Laurence advocated a convex blade; has anyone tried such a knife lately? For clearing a herbaceous border or the like there is nothing to surpass the French "serpette du vigneron"—or Vine-grower's knife (see fig. 17). The blade is crescentic, thin, and well hafted in the handle. *H. E. D.*

Romneya Coulteri (see pp. 10, 22).—After noting the early attempts to grow this fine Poppywort at Tottenham and in South Devon many years ago, and the results of modern cultivation, I am of the opinion that success may generally, if not always, be attained by selecting a suitable soil and situation. The early practice was to plant this Romneya on a rockery or some similarly exposed position, where the plant made only a foot or two of growth during the season, and was thus too feeble to bloom. There is not much to choose between R. Coulteri and R. trichocalyx, because they are very closely allied. Both species will, however, make shoots 2½-4 feet high or more during the season, and flower over a long period, if the soil is well drained to a depth of 2-3 feet, and the situation is on the sunny exposure of a wall or house, or in an angle between two houses, for the plant requires shelter and warmth. This fact I have noted in public and private gardens. I have seen a large bed of R. trichocalyx on the level between two glasshouses in Surrey, and flowering well. Before discarding R. Coulteri Mr. Hicks might well try a sheltered, warm situation. *J. F.*

—— To obtain the best results from this delightful Poppy in the Midlands and further north I recommend planting the roots in a corner of a cold greenhouse, where the quality and number of flowers will be a surprise to everybody. I adopted this system in Hampshire, and from one plant, covering about 8 square yards, it was possible to gather flowers for four months. 20-30 at a time, many of the blooms being 10 inches across. It should prove a good investment to market growers to plant a whole house in this way, as this Romneya gives the finest of cut flowers, which last fresh a long time and are deliciously scented. Romneya Coultéri is not a permanent success in England, as the summers are seldom hot enough and the remainder of the year too wet and dull, although in a sunny, sheltered spot it often does well outside. *E. Richli, Codsall.*

Rabbits and Fruit Trees.—I was much interested in *Market Grower's* remarks under the above heading on p. 19 in your issue of January 11. A few years ago I was employed at a large fruit-growing farm in Middlesex, and found the following remedy to be entirely successful in stopping the depredations of these rabbits: The urine from the stables was drained into a large cesspool; this was then pumped into a barrel as required and mixed with ordinary clay to a workable consistency. A stiff brush was used to paint the bottom of the trees with this solution to a height of 2 to 2½ feet from the ground. Boy labour was employed in the latter operation. Speaking to Mr. J. H. Wood (the landscape specialist), of Boston Spa, a few daws ago, he related to me how, on one occasion, when snow fell to a depth of 2½ feet rabbits had burrowed through the snow in their search for food and completely barked a large number of trees. The above treatment would, I feel confident, prove a sure preventive. *A. W. Harding.*

Hybridisation and Cross-Fertilisation of Flowers.—Those interested in the raising of new flowers will welcome the article by Mr. Heal in the *Gardeners' Chronicle* for January 18. It states plainly the experience of a thoroughly practical man, and one who occupies a very prominent position in that branch of the calling with which he has been so long identified. The creation of the winter-flowering race of Begonias, in which B. socotrana played such a prominent part, stands out as prominently as do the various Javanese Rhododendrons, which originated at Chelsea. It is a great pity that no firm seems now to have taken up the culture of this charming class of plants. One striking feature of Mr. Heal's notes is the great number of crosses which have been carried out among the members of the Begonia family, comparatively few of which seem to have found their way into general cultivation. Among other subjects that the writer failed with was Vallota purpurea, which refused to cross with different allies. I, however, some years ago, raised a large quantity of hybrids between this Vallota and Cyrtanthus sanguinea, frequently known as Gastronema sanguineum. The hybrid had, however, been previously obtained by the late Sir Trevor Lawrence, and was given the R.H.S. First-class Certificate on August 25, 1885, under the name of Gastronema nybrida. A coloured form—roseus—received a similar award the following year. The various small-growing species of Cyrtanthus, such as angustifolius, lutescens, Mackenii, and Macowanii, all hybridise readily with each other. By a continued selection I raised a delightful series of these crosses, but unfortunately they passed out of my hands before I had completed the work. The raising of Fuchsias occupied at one time much of my attention, and several of my raising are now in general cultivation. There were many stumbling-blocks, for some of the most promising would not ripen good seeds, while in others the progeny showed a marked deterioration from the parent. The most satisfactory breeders were, however, in time found and duly noted. *W. T.*

Fig. 16.—Romneya Coulteri: flowers white.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 14.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Messrs. W. C. Worsdell, W. Hales, W. Cuthbertson, Col. Rawson, and F. J. Chittenden (hon. sec.).

Bulbils in Leek Inflorescence.—Mr. W. Cuthbertson showed a large inflorescence of the common Leek in which each of the flowers was replaced by one or more bulbils, as is frequent in many species of Allium. Mr. Cuthbertson, in a long experience, had never met with a similar case.

Substitute for Caraway seed. — Mr. Bowles showed seed of Dill, which is being used as a substitute for Caraway seed. In the opinion of the Committee there seems no reason why Caraway seeds should not be grown in England to supply all our requirements.

Seeds from Salonika.—Mr. Bowles also showed fruits of an Asclepiadaceous plant, which Mr. Worsdell took for identification.

NATIONAL ROSE.

THE most flourishing of the "National" floricultural Societies is the one which devotes its attention to the national floral emblem—the Rose. For forty-two years it has done excellent work on behalf of Rose-lovers, and has steadily increased in power and influence. After nearly five years of war conditions the Society is in a very strong financial position, and though its membership is now 4,860, as compared with 5,500 in 1915, the reduction was due only to the stress and circumstance of war and not to any lack of enthusiasm on the part of growers or of ability on the part of the officers and Council.

The numbers and enthusiasm of the members present at the Holborn Restaurant on Tuesday last, on the occasion of the 42nd annual meeting, were evidence of the prevailing interest and satisfaction with the conduct of affairs. The president Mr. E. J. Holland, presided, and many notable rosarians, including ladies, were present.

The usual formal business was quickly disposed of, and the Report of the Council, as printed and in the hands of members present, was taken as read. We give the following extracts :—

The Council is deeply grateful to members for their staunch support during an exceedingly anxious time; and the fact that the society has been able to continue its work, strengthen its financial position, and emerge full of vitality after four years of war, must be regarded not only as proof of a deep and abiding love for the Queen of Flowers, but also as a strong testimony to the valuable work which has been done by the society.

In 1917 the Show programme was greatly curtailed, in view of the urgent call to National Service; but in 1918 it was found possible to hold three meetings The Spring Show took place on May 7, at the London Scottish Drill Hall, in connection with the Royal Horticultural Society, and beautiful collections of flowers were staged. On Thursday, July 4, the Summer Show was held at the Royal Botanic Gardens, and the fine display of particularly bright, clean blooms, the comfort of the arrangements, splendid weather, and the happy reunion of rosarians after the break in 1917, conspired to make the gathering a conspicuous success. The pleasure of all present was greatly enhanced by the fact that Her Majesty Queen Alexandra graciously honoured the society by paying a prolonged visit to the show, and expressing her admiration of the beautiful exhibits. The takings were given to the British Red Cross Society. The Autumn Meeting was held on Tuesday, September 10.

The "Rose Annual" for 1918 was sent to all members in February last. During the year numerous additions have been made to the society's library at 25, Victoria Street, and many of the books most in demand have been duplicated.

The financial position of the society continues satisfactory. The total receipts for the year, including a balance of £321 4s. 5d., brought forward from last year, amount to £3,262 4s., and the total payments for the same period to £3,191 9s. 4d., leaving a balance at the society's bankers on December 31, 1918, of £70 14s. 8d. During the year the Council invested £1,000 in War Bonds.

Arrangements have been made to hold a Spring Meeting at the London Scottish Drill Hall, Westminster, on Tuesday, April 29, 1919; the Great Annual Summer Show at the Royal Botanic Gardens, Regent's Park, on Wednesday, July 2; a special meeting for new seedling Roses at the London Scottish Drill Hall, Westminster, on Tuesday, July 15; and an autumn meeting in the same hall in September.

The Council desires to record its appreciation of the good work done by local secretaries and others in securing new members, and foremost amongst those who have been particularly successful, Mr. C. E. Cant, Mr. Elisha Hicks, and Mr. A. Bide must be mentioned. It also acknowledges with gratitude the services rendered by Miss Willmott, V.M.H., one of the society's vice-patronesses.

Before moving the adoption of the report and the financial statement so ably presented by Mr. S. A. R. Preston-Hillary, the president referred to the absence of Mr. Chas. E. Shea, who was unable to attend, as Mrs. Shea had sustained a severe accident. At Mr. Holland's suggestion a telegram of sympathy and hope was sent to Mr. and Mrs. Shea.

Mr. Holland briefly reviewed the work done in 1918, and stated that the Council had recently received invitations to hold provincial shows at Norwich and Weston-super-Mare; he hoped that it might be possible to accept one of them, and in such case the Show of Seedling Roses would not be held in London on July 15. The Rev. J. H. Pemberton seconded the motion, and expressed the hope that at an early date the Society might hold its Metropolitan Show where ampler space could be afforded the exhibits, such as at Chelsea Hospital. He suggested that an editorial staff might be necessary in the near future to relieve the pressure of work now falling upon the hon. secretary, Mr. Courtney Page. The report and accounts were adopted.

Mr. H. R. Darlington was elected President, and Dr. A. H. Williams Vice-President; the other officers were re-elected, and all except two

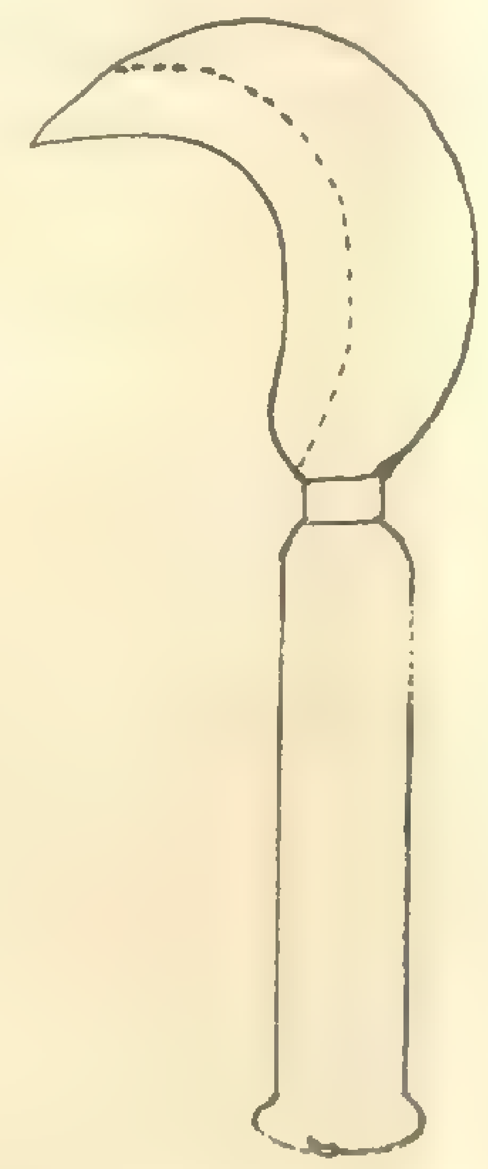

FIG. 17.—SERPETTE DE VIGNERON (VINE-GROWER'S PRUNING KNIFE).
(One-third actual size.)
(See p. 45.)

of the members of the 1918 Council were returned to office, with Mr. F. M. Elgood, Dr. A. R. Waddell, and Lt.-Col. E. B. Walker added. In connection with the election the desirability of a postal ballot was suggested; a brief discussion ensued, and finally, on the motion of Mr. Elgood, seconded by Mr. Chaplin, the meeting recommended the Council to consider means whereby a larger number of members might take part in the election of officers and Council.

Mr. Darlington having taken the chair, as the new president, Mr. Holland was accorded a very hearty vote of thanks for his services so ably and enthusiastically rendered during two years of office.

An interesting part of the proceedings was the presentation of a Dean Hole Memorial Medal to the Rev. F. Page Roberts; a similar honour was voted to Mr. George Paul, who was not able to be present.

Thanks having been accorded to the officers and Council, to which Mr. Courtney Page and Mr. Preston-Hillary responded, the business was brought to a close, but all sorts of matters concerning Roses and rosarians were discussed informally in the social after-meeting, where tea and light refreshments were served, and a programme of music provided.

ROYAL CALEDONIAN HORTICULTURAL.

JANUARY 8.—The annual general meeting of this society was held in Dowell's Rooms, 18, George Street, Edinburgh, on this date. Mr. McHattie, the senior vice-president, was in the chair, and there was an attendance of about 20.

It was announced that in response to the queries sent out to growers regarding the varieties of Apples grown in the different districts of Scotland, replies had been received from 50 growers, and it was proposed to circulate this information for the use of the members. It was also announced that Mr. G. P. Berry and Mr. Banks, of the Board of Agriculture, were preparing, for the Society, papers on hardy fruit growing and fruit preserving respectively, which would also be published.

It was agreed to remit the question of holding a show in Edinburgh in the autumn to the Council for consideration and decision.

The Right Hon. Lord Newlands was elected president in succession to Lord Elphinstone; Mr. E. P. Laird was elected to the vacant vice-presidency caused by the retirement by rotation of Mr. McHattie, and Messrs. J. D. Adair (of John Downie), Edinburgh; W. Galloway, Gosford Gardens, East Lothian, and Thos. J. Gray, Edinburgh, were elected to vacancies on the Council.

The accounts showed a balance of income over expenditure of £40.

NORFOLK AND NORWICH HORTICULTURAL.

MR. SYDNEY MORRIS, of Earlham Hall, presided at the annual general meeting of the Norfolk and Norwich Horticultural Society on January 11 at the Castle Museum. The report submitted by the Committee contained an excellent record of work accomplished. There are 172 members, food production has been encouraged, flowers not neglected, £50 invested in War Bonds, and a balance in hand of £80 12s. A suggestion that the 1919 show be held at Eaton Park in conjunction with the Norfolk Agricultural Society's show in June, was not accepted, but it was agreed to omit the spring show, hold a Rose show at Earlham Hall on Thursday, July 10 (in conjunction with the National Rose Society's show), and a Chrysanthemum show on November 20, 21 and 22.

Officers were elected as follows: Mr. Sydney Morris, president; Dr. C. A. Osburne, vice-president; Mr. E. G. Buxton, treasurer; Messrs. Bach and Preston, auditors; and Mr. E. T. Pollard, hon. secretary, with Mr. Richard Preston assistant hon. sec. The retiring members of committee were re-elected, and Mr. J. A. Christie was added to the committee.

HIGHLAND AND AGRICULTURAL OF SCOTLAND.

JANUARY 8.—It was reported at the annual meeting of the Highland and Agricultural Society of Scotland, held in Edinburgh on this date, that the directors had agreed to hold the "victory" show in the meadows, Edinburgh, which had been offered by the Edinburgh Town Council for the purpose, on July 8 and succeeding days. It is proposed to throw a temporary bridge across the centre walk in order to connect up both the east and west meadows, and the total area available for the show will thus be about 46 acres.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JANUARY 13.—The monthly meeting of this Society was held in the R.H.S. Hall on the 13th inst., Mr. C. H. Curtis presiding. Four new members were elected. One member was allowed to withdraw interest amounting to £5 1s., and one member over the age of 70 years withdrew £2 from his deposit account. The Army Forms of Privates G. H. Crane and H. G. Hedges were received, also the death certificate of one deceased member, and the sum of £54 10s. 11d. was passed for payment to their respective nominees. The sick pay for the month on the ordinary side amounted to £71 15s. and on the State section to £37 4s. 2d., and maternity benefits to £3.

CROPS AND STOCK ON THE HOME FARM.

MAKING NEW AND REPAIRING OLD ROADS.

CONTINUED wet weather is seriously retarding land operations, especially on heavy soil. Opportunity should be seized to employ the horses and men on the improvement of existing roads and the making of new ones where they would be an advantage to the farm and the estate.

New roads are often made in a slipshod manner, and the commonest error is that of failing to provide a good foundation. The base of a new road should be made in true convex form in the same manner as the finished surface, with a good fall from the centre to the outside, so as to keep the centre dry. The rapid removal of surplus water may be provided for by a single main drain down the centre, or one on each side on the margin, whichever is considered the most suitable. The depth of "metal," i.e., stones, clinkers, broken bricks, or whatever material is available, must be governed by the amount of traffic such roads are likely to carry; 10 inches is none too much for the base, with a 2-inch layer of fine material over it. In the base the largest of the material may be used, even stones 1 foot thick need not be broken, as these, in the cartwheel line, will resist the heaviest traffic. Where there are very deep holes in the base of the road hedge trimmings or small bundles of fine coppice wood would answer the purpose if laid cross-wise over such inequalities, last many years, and provide good drainage for the hard material above. When the base is made and the heavy material filled in, the road should be well rolled to prepare it for the coating of gravel or small stones.

When rolling a newly made road, wide or narrow, the roller should first be used on each side of the road, and then in the centre, to ensure the desired shape.

Roads in need of repair are generally those at the entrances to fields by gates, where there are frequently pools of water or mud. First clear away the latter and level up the hole with dry chalk, which provides an excellent material for such foundations, where frost cannot affect it. Chalk is of no value near the surface, as frost crumbles the layers, and the first shower afterwards turns the spot into a quagmire.

CUTTING HEDGES.

Hedge-trimming is useful work, especially around arable fields, where high fences are harmful to crops. Hedges harbour sparrows and rabbits, both of which are a nuisance and do much harm to Corn crops, especially Wheat approaching the ripening stage. Hedges around arable fields are not required for shelter; crops are better without them, and if sheep are turned on the land close hurdles are sufficient.

Where hedges around grass fields have become overgrown and thin at the base they should be "splashed" by cutting a piece 6 inches long on the top side of the main shoot, some few inches from the base, at a point where it is wished to "lay in" this part. Such "splashing" enables the hedge to be put into shape again, as the main stems are bent and laid in obliquely one above another until the desired height—4 feet or 6 feet—is reached. By this method an old hedge is at once converted into a new, rigid, live fence. *E. Molyneux, Swanmore Farm, Bishop's Waltham, Hants.*

Obituary.

George Bunyard.—As these pages are being passed for press, news reaches us of the death, on the 22nd inst., of Mr. George Bunyard, V.M.H., Maidstone.

Edouard Michel.—We learn with regret of the death, in his 84th year, of Monsieur Edouard Michel, who was for many years director of Messrs. Vilmorin-Andrieux & Co.'s Paris establishment and trial grounds. The name of Edouard Michel will always be connected with the improvement of vegetables and flowering plants. His work, of permanent value to horticulture, was continued over many years; so long ago as 1900 M. Michel retired from active work.

TRADE NOTES.

PROHIBITION OF PLANT IMPORTS INTO AMERICA.

MR. A. J. JACKMAN, of Messrs. George Jackman and Son, Woking Nurseries, Surrey, sends the following remarks on the new regulations issued by the Federal Horticultural Board of the United States Department of Agriculture governing the importation of plants, etc., into the United States, to which we referred in the issue for January 4, p. 12. The new regulations come into force on June 1 next :—

The regulations are of a most drastic nature, going so far as to exclude the importation of all nursery stock, with the exception of "certain bulbs, Rose stocks, fruit stocks, cuttings, scions and buds, and seeds of nut, fruit, forest and other ornamental and shade trees, and of hardy perennial ornamental shrubs," for which permits must first be obtained.

The reason given for this measure is said to be owing to certain injurious insects and fungous diseases which might be imported from "Europe, Asia, Africa, Mexico, Central and South America, and other foreign countries and localities."

I have no desire to make any remarks with regard to exportation from countries other than our own. Is it not a fact, however, that the pests to be found here are mostly far worse in the States, and that in some cases they have been traced to importation from that country? One can commend the United States authorities for taking all necessary steps to keep down these pests, but to exclude all nursery stock regardless of its condition and origin is beyond all reason.

From information I have received I have reason to doubt whether some other motive may not be at the bottom of this new Act, and that it has not been adopted solely as a means of excluding pests. The American firms who import stock are, I understand, not at all in favour of their Board's action. Since July 1, 1916, the Government of the United States has introduced rules and regulations governing the importation of nursery stock into the States, whereby it has been impossible to send any class of stock, before it has been examined and passed as free from all scheduled pests, by an expert from the Board of Agriculture or some other approved person, an original certificate accompanying the invoice and a copy certificate being affixed to each case or package.

This arrangement has, I believe, worked satisfactorily up to the present time so far as this country is concerned, though if isolated cases of neglect in shipping affected plants have occurred, it is surely up to the United States authorities to demand more minute inspection of stock from the localities affected rather than prohibit the importation of all nursery stock.

Such a measure must affect the British nurseryman very adversely. Several firms have for years made special provision to supply the American trade; they have entered into contracts to grow yearly certain classes of stock, and have cultivated varieties of such plants as Rhododendrons, Roses, Conifers, and ornamental shrubs which are best suited to the American climate, but are of little value for home trade. What is to happen to all this stock, some of which has taken at least seven years to mature?

This, however, is not the only aspect of the matter. The same prohibition also applies to France, Holland, Belgium and Germany, countries which ship tens of thousands of pounds' worth of nursery stock to the States annually. The growers are not going to destroy their stock if they can get rid of it elsewhere at some price. Are we going to allow them to send it here? The nursery trade of this country has been seriously handicapped by foreign dumping for years. Is that to be increased tenfold? It is clearly incumbent on the Government to take immediate action with a view to getting these new prohibitive regulations rescinded, and to prevent the dumping of foreign stock in this country.

GARDENING APPOINTMENTS.

Mr. J. B. Ross, as Gardener to Lord Justice WARRINGTON, Clyffe Hall, Market Lavington, Wiltshire.

Mr. Jas. T. Irvin, recently Gardener at Sunninghill Park, Ascot, Berkshire, previously General Foreman at Lockinge Park, Wantage, Berkshire, and at Sherborne Castle, Sherborne, Dorsetshire, as Gardener to Miss WYATT, Heathfield, Ascot, Berkshire.

Mr. G. Allison, late Gardener at Rock House, Cromford, Matlock, as Gardener to R. J. P. THOMAS, Esq., Elcot Park, Kintbury, Berkshire.

F. R. Kime, who has served in H.M. Forces during the past 3 years, has now resumed his duties as Gardener to H. TAYLOR, Esq., Wissahicken, Eaglescliffe, S.O., Co. Durham.

ANSWERS TO CORRESPONDENTS.

COELOGYNES SHRIVELLING: *G. M. S.* If your Coelogyne is a plant of the cristata species the treatment you mention, as to temperature and watering at this season, should be quite satisfactory. The shrivelling is doubtless due to the plants receiving insufficient light last autumn for the proper ripening of the pseudo bulbs. This slight shrivelling need cause no alarm, as a more copious supply of water afforded after the flowering season will soon cause the pseudo-bulbs to become plump again.

FLAGGING CUCUMBER LEAVES: *P. L.* When bright sunshine follows a period of dull weather the leaves of Cucumbers generally flag for a few hours, but if there is sufficient moisture in the atmosphere and in the soil in which the plants are growing, flagging should not be prolonged even in continued bright weather. Over-cropping, crowded growths and a lack of suitable plant-food may each or all be responsible in some degree for the flagging foliage, provided no disease is present.

NAMES OF PLANTS: *W. M. M. D.* A form of Cypripedium Leeanum—a hybrid obtained by crossing C. insigne with C. Spicerianum. —*F. E. R.* 1, Acacia dealbata; 2, A. Baileyana; 3, A. decurrens.—*S. H.* 1, Viburnum Tinus; 2, Skimmia japonica; 3, Cotoneaster frigida; 4, Euphorbia splendens; 5, Reinwardtia trigyna.

RENOVATION OF A NEGLECTED LAWN: *W. B.* Rake off all decayed and rough grass with a wooden rake, and with an iron rake pull out as much of the moss as possible. During a spell of fine weather mow the lawn with a scythe, but do not cut the grass too closely or bare patches may appear if severe frost follows. The presence of moss suggests that the lawn is not sufficiently drained, therefore, if labour is available, a few lines of drain tiles should be inserted to carry away surplus moisture. Dress the lawn with super-phosphate of lime at the rate of 4 lbs. to each 40 square yards, and spread finely-sifted soil, such as old potting compost, over the grass. The soil dressing will soon disappear from the surface, and it will encourage fresh root-action and close growth in the grass. Sweep the lawn lightly at intervals, but do not brush up the soil dressing; roll with a light roller in fine weather. As soon as the grass begins to grow freely mow it once or twice with a scythe, and then use the machine with the knives set rather high. If the knives are set a little lower at each mowing the sward will soon become even, and the mowing machine will then do its work easily. We have in mind a tennis lawn brought back to first-rate condition in this way after two years' neglect; the work was commenced in February and the lawn was fit to play on in May.

WHITE FLY ON TOMATOS: *P. L.* As all the means you have adopted for the extermination of the White Fly (Aleyrodes vaporariorum) in Tomato houses have failed, we recommend cyaniding the houses on several occasions before planting. You will find a note on "Cyaniding Tomato Houses" in *Gard. Chron.*, October 12, 1918, p. 154.

WIREWORMS: *S. J. S.* The various points raised in your letter are fully dealt with in another part of the present issue.

Ranunculu , red, per d z. bun	18 0-24 0
Roses, Safrano, per packet...	2 6- 3 6

REMARKS.—Daffodils are now arriving in larger quantities, mostly from home growers. The varieties so far offered are Golden Spur, Princeps, and Henry Irving. Snowdrops are increasing in quantity daily, and the majority are very fine blooms. Prices are becoming lower. Lilies-of-the-Valley appear to be sufficient for the demand, and prices remain as quoted last week. Roman Hyacinths are arriving in limited quantities, and are soon cleared. High prices are still maintained for English single Violets. Large quantities are being sold. Very few of these blooms are being sent from the south of France; they are too long in transit, and of the few packages that are sent, many arrive here unsaleable. Two large consignments of French flowers arrived last week. These included large consignments of Mimosa and some Anemones and Ranunculus. Many of these packages showed the effect of the long journey. Paper-white Narcissi also appear to be a little weatherbeaten before despatch, and many packages have to be cleared at low prices. The consignments from the Channel Islands consist of Paper-white Narcissus, N. grand primo, N. Soleil d'Or, white Freesia, Anemone fulgens, and single Violets.

Fruit: Average Wholesale Prices.

MISCELLANEOUS.

THEY'RE NOT STICKY.

Beacon Oilskins are quite free from any stickiness, and, what is more important, they never fail to keep out the hardest rain or sleet. Hundreds of farmers, gamekeepers, and other outdoor men, women, and children wear them because they bring weather comfort. You ought to wear them if you want to keep dry in any deluge. The Beacon Booklet will help you to choose the style you need. Children's Coats from 16s. 6d., Men's from 25s., Ladies' Smart Oilskins, 28s. 6d. Long Leggings from 5s. Sou'-westers, from 3s. Your money back if they don't satisfy you entirely. Send a postcard to-day for our Free Booklet of "Weather Comfort," — Send now—before you forget—to BARBOUR'S, LTD., 66, BEACON BUILDINGS, SOUTH SHIELDS. (2)

WEEDS! WEEDS! WEEDS! Now is the time to destroy them before casting their seeds. If your paths are cleared now they will remain clean for the best part of next year. Our Weed Killer is safe to handle, non-poisonous, will not harm birds or animals, is a powder; only requires sprinkling on the weeds.

1 cwt. sacks, 20s., free on rail, London.

GARDENER (SECOND), chiefly Inside; cottage and garden provided; also good MAN, Outside; good wages. — W. TRATT, Holywell Park, Wrotham, Kent.

SITUATIONS VACANT continued on page ix

FLOWERS from SEED

THE need for flowers in the garden and in the house has been more than ever felt during the past summer. In the earlier days of war, flowers were almost regarded as an unnecessary luxury, but the lack of them has served to show how invaluable they are in these times, as evidenced by the keen desire to secure bulbs for autumn planting. Flowers from seed are the cheapest and most effective means of beautifying our gardens, and a little time and thought devoted to the selection and growing of some of the hardier and more easily cultivated kinds will be well repaid.

Annuals, such as Godetias, Clarkias, Eschscholtzias, Larkspurs, and Poppies, as well as Asters, Stocks, and Phloxes, flower freely when sown in the open ground, if the soil be well prepared and the seedlings severely thinned to give plenty of room for root growth. Nearly all the early-blooming Annuals will flower a second time if cut when the blossoms begin to wither. Sunflowers and Lavateras add brightness to shrubbery borders, and the dwarf Sweet Alyssum, if sown profusely as an edging, gives a charm to the garden from June till late autumn. These are only instances of what can be done to enliven our gardens at small cost. In spring, Wallflowers, Sweet Williams, Pansies, Polyanthus Myosotis, and the Siberian Wallflower (Cheiranthus Allionii) will follow Crocuses and Daffodils and add to the beauty of the May garden till the spring-sown Annuals take their place.

BRITISH LICHENS.

THERE are certain indications of an increasing interest in the lichen flora of the British Isles. Perhaps the most reliable of these is the frequency with which contributions, mostly of an ecological character, have been made to the literature of the subject, for within the past seven years important communications have been published in the scientific journals respecting investigations that have been carried out in various districts of Great Britain and Ireland so widely separated as Elginshire and Devonshire, Norfolk and Lancashire, Howth Head and Clare Island. This affords proof that the work has not been solely that of a small number of enthusiasts in a restricted area, but that it is due to a more general awakening of interest to the importance of lichens as members of plant communities.

The publication of the present volume of *A Monograph of the British Lichens*,* on modern lines, was particularly opportune, for it was issued at a period when the need for the completion of the work, which was known to be in the very capable hands of Miss A. Lorrain Smith, was being freely expressed. The publication of Part II. of the *Monograph* (1911) did much to lead to the adoption, by British lichenologists, of a uniform nomenclature which had been based upon an exhaustive study of synonyms. With the completion of the *Monograph*, there should be no occasion for confusion to arise respecting the present name of any British lichen.

An entirely new feature of this volume is the addition of an explanatory introduction, pages viii. to xxiii., which conveys in a clear, terse style, information concerning the structure, morphology, reproductive organs, physiology, and classification of lichens. The structures peculiar to the lichen thallus, as soredia, isidia, cephalodia and cyphellae, have received special attention. The short paragraph allotted to each of these structures is more informing and much to be preferred to the short definitions appearing hitherto only in the glossary. The gall-like outgrowths which form the hooded ends of the laciniae of Physcia hispida, caused by a mite which eats away the cortex and stimulates the formation of gonidial tissue, are mentioned in connection with the description of the plant on page 241. In paragraph four, page viii., the general opinion is accepted that the algal elements of the lichen thallus multiply by division within the thallus, and that zoospores are never produced except in cultivation outside the thallus. The statement is probably based upon the fact that the morphology and physiology of algal cells, isolated from the lichen, have within recent years been followed more thoroughly than that of algal cells developing within the thallus. The results gained by the adoption of culture methods with lichen gonidia may lead to the identification of the particular alga that is in symbiotic relationship with a fungus; but it does little to add to our scanty knowledge of the morphological changes that take place within the algal cell under symbiotic conditions, and about which books on lichenology and text-books of botany are so vague. It is frequently stated that the algal elements of the lichen thallus multiply by division within the thallus, but the kind of division, vegetative or otherwise, is not described nor is a dividing cell figured. It has, however, been demonstrated, since this book was in print, that a non-vegetative cell division, sporulation, does take place, and that this brings about a great increase in the number of the gonidia.

The plan of classification adopted is based primarily upon the structure of the fruit, and is followed by the development of the lichen plant as a whole. Lichens containing blue-green algae (Myxophyceae) are considered before those containing bright green or yellow algae (Chlorophyceae). Under this system British lichens fall into two great series—I. Gymnocarpeae, in which the fruits have more or less open discs. II. Pyrenocarpeae, with closed fruits. The first of the above is further divided into three sub-series:—(1) Coniocarpineae, apothecium partly closed, retaining the spores when mature in a powdery mass. (2) Cyclocarpineae, apothecium with open disc; spores ejected when mature. (3) Graphidineae, apothecium with elongated narrow disc. This volume includes descriptions of the British lichens that belong to the first two of the sub-series.

Following the description of each order (family) is a key to the genera. Some of the larger genera are further divided into sub-genera. This method should aid the student to track down a species to within quite narrow limits and thus save valuable time.

The thorough revision, that is evident throughout the volume, necessitated the introduction, according to the rule of priority, of names that replace very familiar ones. Various changes that have been made may be illustrated by reference to the genus Cladonia, which will be found to include as sub-genera the genera Cladina and Pycnothelia of the first edition.

Under Cladonia, as now understood, there are forty one species, whereas in the first edition the three genera referred to contain forty-three species. This difference is caused by the union of similar species and by their reduction to varieties. For instance, Cladonia foliacea Willd. (= C. alcicornis Floerk.) now includes the former species C. firma and C. endiviaefolia as varieties. Sub-species are raised to species and one entirely new lichen is added.

At the end of the volume are seventy-one plates, which include on an average six figures; each plate illustrates a typical species of the genera described in the book. The drawings are by Mr. P. Highley, and are similar in character to those illustrating Part II. (1911).

Miss Lorrain Smith has succeeded in producing a book of great merit, and, beyond question, the complete *Monograph* will become the standard work of reference for all students of lichenology.

* *A Monograph of the British Lichens*. A Descriptive Catalogue of the Species in the Department of Botany, British Museum. Part I., second edition. By Annie Lorrain Smith, F.L.S., Acting Assistant, Department of Botany. (London: Printed by order of the Trustees of the British Museum.) Price 30s.

BULB GARDEN.

LILIUM PHILIPPINENSE.

The note on p. 238, from *Plant Immigrants*, No. 140, regarding the qualities of Lilium philippinense, states that the species is said to be destined to become of great value both to commercial and private growers, and to be especially noteworthy for the short time which elapses between potting and flowering. Beautiful as this Lily is, from my experience of it I have grave doubts about it proving to be the success which is anticipated, and I have yet to learn that its culture has been taken up commercially. The species was first discovered by Gustave Wallis, the collector, on the Island of Luzon, one of the Philippines, in July, 1871. Two years later, namely, on August 6, 1873, it was, when shown by Messrs. James Veitch and Sons, given a First-class Certificate by the Royal Horticultural Society. In 1884 I had many hundreds of collected bulbs under my charge, and found that though they flowered well the first season they proved to be very unsatisfactory afterwards. Some years later I made a note of this Lily in flower in Mr. Ware's nursery at Tottenham. I have an idea these results were from freshly imported bulbs. In its very long, slender tube this Lily bears a considerable resemblance to the Himalayan L. Wallichianum, which is also a difficult Lily to establish, and seems now to have almost dropped out of cultivation. Another beautiful Lily well known some thirty years ago from imported bulbs is Lilium neilgherrense, with flowers more or less of a primrose tint, and in some examples at least with exceedingly long tubes. My experience of this species is that the bulbs, if sufficiently developed, flower well the first season, but very poorly the next. Like Lilium philippinense, this is essentially a greenhouse species. If the Philippine Lily is to be of commercial value it will be necessary to grow it under sub-tropical conditions, such as obtain in the Island of Bermuda, where the form of L. longiflorum known as Harrisii has proved to be a success. So far as one can judge, Lilium longiflorum is still the species upon which we must depend to keep our markets supplied with white Trumpet Lilies. *W. T.*

ON INCREASED FOOD PRODUCTION.

ONION THE URN.

While frankly admitting there are many excellent varieties of Onions on the market today, I consider, judging from several years' experience in growing and comparing most, if not all the well-known varieties, the best for general purposes, especially for keeping, is The Urn, raised some years ago by Mr. Taylor, The Gardens, Byram, Ferrybridge, Yorks. The variety does not come absolutely true from seed, but about 85 per cent. to 90 per cent. of the seedlings are true. The variety is urn-shaped, and to my mind this is a great advantage to the consumer, as there is very little waste when the base of the bulb is cut off preparatory to use. The bulb is very solid, and consequently weighs heavy, whilst the keeping properties are all that can be desired. I have been using bulbs of The Urn, quite sound, year after year, long after those of other varieties have become quite useless.

From a plot of 200 square yards I had a crop of 16 cwt. of bulbs of excellent uniform quality. The treatment was quite ordinary throughout.

Fig. 18.—A fine crop of onions of the Urn variety.

The seeds were sown in boxes in January, and the seedlings eventually planted in their permanent quarters without any special treatment of any kind. *W. H. Dobson, Stapleton Park Gardens, Pontefract.*

POTATO MAJESTIC (see p. 20).

Since my notes on this Potato appeared in your columns (see p. 260, Vol. LXIV), I have had several letters sent to me on the subject. I think my correspondents should have sent them to you. I venture to send you two extracts which have a distinct bearing on the question of cutting tubers of Majestic for planting.

Mr. G. W. Leak, of Messrs. R. H. Bath, Ltd., Wisbech, writes: "I am all for Majestic, judging from this year's test. We lifted about 16 tons per acre, free from disease. The quality is grand. Some of the tubers, weighing 14-15 oz., were as smooth and shapely as you ever saw any of Up-to-Date selected for exhibition. With respect to your remarks on the cutting of the tubers, I may say we cut about half ours, and planted them alongside the uncut ones. The results, so far as we could tell, were precisely the same. There were no failures, and the crop was just as heavy from the cut as from the whole sets. They were cut the day of planting from the chitting trays and limed as usual."

The headmaster of Edward Street Senior Boys' School, Grimsby, writes: "After reading your article on the Potato Majestic in *Gard. Chron.*, December 28, 1918, I thought you might be interested to know how I succeeded on my school allotment with that variety.

"I bought 7 lbs. of Majestic, consisting of 38 tubers. These, after sprouting, I divided into 82 sets, cutting them 1½ hour before planting, and dusting the cut surfaces with quicklime. Only two sets failed, and these, on examination, I found to be eaten off by some ground pest.

"One Potato I cut into five parts, three of which I dug up, when half-grown, on August 3 for show purposes, getting 16 lbs. of small and moderate-sized tubers, and in addition nine tubers for competition (not so bad for three-fifths of a Potato set). The total crop, lifted in October, was 4 cwt. 2 st. ¾lb.—about 34 tons per acre. The heaviest root yielded 11 lbs. 15 oz.

"It may also interest you to know that as an experiment I planted alongside of Majestic a row each of Arran Chief, King Edward, President, Queen Mary, and Carter's Monarch, and, although I treated them exactly the same as the Majestic, the crop was in no case more than half that yielded by the last variety."

In Mr. Robertson's second note (p. 32), he very clearly brings out the difficulty of obtaining "seed" sized tubers of this Potato. If growers for seed have a like experience—and they have—what are they to do with the 15 cwt. per ton of large tubers? The best that merchants can do this year is to keep back the very large tubers for planting again themselves, and give buyers as good a sample as possible. After what has been stated in *Gard. Chron.* no one need fear to cut their sets.

In my lecture at the Mansion House last February, I gave Majestic and Kerr's Pink as "tips" for 1918, and I think I was right. For 1919 I gave Arran Comrade, a fine, shapely second-early variety, immune to wart disease, raised by Mr. McKelvie, of Arran, the raiser of Arran Chief. Those keenly interested in new varieties of Potatos should endeavour to secure a few pounds of it. *W. Cuthbertson, Duddingston, Mid-Lothian.*

SUGAR PARSLEY.

The Sugar or large-rooted Parsley is not much grown, though it is a distinctly useful vegetable. Its food value can hardly be less than that of the Parsnip. Its freedom from the pervading rankness of the latter root makes it edible for a number of people who, like myself, regard the Parsnip as almost, if not quite, inedible. Either served alone or as a constituent of a stew, it may appear on the table; it will blend well with fish, and is, in fact, an essential ingredient in a "water souchet." Also, during storage in the winter, a supply of Parsley leaves may be obtained from it; though very fairly hardy and not damaged by frosts in the open, we usually store it under cover during the cold weather. Last season I weighed the crop grown on a strip about 1½ by 9 yards; the plants were fairly carefully singled when quite small to about an inch or so apart, a process which, if laborious, is better with all root crops than the usual method of spacing first and singling later. In fact, with Carrots a singling to a couple of inches without further thinning suffices to get a heavy crop of useful-sized roots. The final thinning in the case of the Parsley left the plants only some 4 to 6 inches apart, which accounts for the smaller sizes being in a majority. The total number of roots was 183, weighing in all 84 lbs.; they were graded into three lots: (1) Larger, 3½ inches or more in diameter at the top, 9 inches or more long, tapering to a thickness of ⅜ inch: 43 roots, average weight 12 oz. (2) Medium, smaller than the above, but of fair size and shape; 102 roots, average weight 6 oz. (3) Small and forked; 38 roots, average weight 7 oz.

It should be added that the real crop was rather larger, as a certain number had been pulled and consumed before the crop was lifted.

Perhaps it is unjust to compare the produce of a strip of Parsnips, which received scant attention, and was only put in as a war-time measure; moreover, they were attacked by some disease of the leaves which retarded their growth. The total crop consisted of 120 roots, weighing 90 lbs. Of these, the larger ones amounted to 70 in number, with an average weight of 1 lb. 2 oz., and 50 smaller, averaging about 6 oz.

With regard to pests, the Sugar Parsley does not seem to be affected by the Carrot or Celery flies; it is not so prone to destruction by slugs as the Carrot. I have noticed a few roots affected with some softening disease, with the nature of which I am not acquainted. There seems to be scope for improved races—at any rate, so far as concerns the strains that I have tried from English sources, from which I have never had roots more than about 1½ to 2 inches in diameter at the crown. The strain that I have grown for some years was of Continental origin, and in growing plants for seed every two or three years it seems wise to have at least three plants to draw from. This is especially the case with Umbelliferous plants, as the blossoms, though freely produced, will sometimes fade without forming seeds. Sometimes I think that this is due to want of water at the critical setting stage. Probably it is inadvisable to use seed that is older than three, or at most four, years. *H. E. D.*

THE WINTER ACONITE.

The Winter Aconite, Eranthis hyemalis, is very charming when established in the greenery of a policy and allowed to seed and sow itself in a natural way. Major Maxwell, of Kirkennan, Dalbeattie, has annually a delightful display of the golden flowers of the Winter Aconite in his grounds at Kirkennan, and in the early days of the year. The bright flowers, with their Elizabethan ruffs of green, accord well with the grass in which they grow. After seeing the Winter Aconite in many places I may say that the scene at Kirkennan excelled those provided by the Aconite anywhere else, although in some places there are certainly more plants. *S. A.*

NOTES ON IRISES.

IRIS UNGUICULARIS.

Iris unguicularis (see fig. 19) is one of the most delightful and valuable of hardy winter-flowering plants, but it is comparatively seldom that the best use is made of it. Those alone can fully appreciate this Iris who have gone out in the dreariest of wintry weather to pick a handful of the buds, and who have then watched them unfold rapidly in a warm room and fill it with their fragrance. Only too often this Iris is found growing in almost sunless or exposed positions, where few buds develop, or else the plants have been allowed to develop into such a tangled mass of growths that they do little more than provide shelter for slugs and snails, which make short work of the buds before the time has come to pick them.

It is surprising for what a number of years a plant of this Iris will continue to flourish undisturbed in even the poorest of soil. The root fibres penetrate to a great depth, and seem to enjoy the hungriest of sand. But, in spite of the fact that some flowers are produced even from the most matted tangle of growth, yet my experience has been that after a few years it is really better to lift and break up some of the clumps, even though there will be a partial loss of flowers for the first ensuing season. The plants may be moved with success early in September, though I am inclined to think that the operation is equally, if, indeed, not more, successful when carried out in April. At any rate, a year ago last April, I decided that the time had come when two huge clumps must be divided if they were not to dwindle away, for they had remained undisturbed for ten years at least. The sandy soil underneath them had solidified to such an extent that it was almost as hard as the sandstone which forms the core of this hill. Not wishing, however, to make the soil too rich, for this would produce an abundant growth of foliage and an almost entire absence of flowers, I contented myself with merely digging up the soil about three spits deep and incorporating in it a certain amount of old leafsoil and a liberal dressing of basic slag. I then broke up the clumps into small pieces, and replanted them at once, for there were signs of new root-growth. This I encouraged during the ensuing summer by soakings of water in any period of drought and by occasional light dressings of nitrate of potash. Last winter, as I had anticipated, there were comparatively few flowers, but this year I am being rewarded by a most abundant crop of blooms. Five or six times the space occupied by the two clumps which I broke up is now covered with vigorous growths, which are flowering profusely. Fortunately, we have so far escaped from any exceptionally sharp frost, such as sometimes kills the buds in wholesale fashion—a possibility which suggests that it is quite worth while to put an old light over the plants when severe cold may be expected.

It is unfortunate that the uncouth name of unguicularis is older, and therefore botanically more correct, than that of stylosa, which is not only more euphonious, but also peculiarly appropriate, for it refers to the curious way in which the three narrow style-branches rise together in a slender column for nearly an inch before spreading outwards. This is a feature which, if I remember rightly, does not occur elsewhere among Irises, and the species is also unique in that the anthers and the filaments adhere firmly to this column and to the style-branches, though they are not actually joined to them.

There are several local forms of this Iris, the best being probably the common Algerian variety, with lavender flowers. There is at least one, and probably more than one, white form, but the colour is an ivory-white, and the shape is less pleasing than that of the type. The Greek forms have more scanty foliage, flower only in spring, are of a deeper purple colour, and have a stronger, sweeter scent, more like that of fresh honey. Dwarf forms of this variety are found on some of the Greek islands, e.g., Cephalonia, while in Southern Asia Minor there are forms with very narrow grassy foliage and slender, narrow petalled flowers of no great beauty. Curiously enough, the form from the Eastern end of the Black Sea, which has been introduced under the name of I. lazica, has broader foliage, of less leathery texture than that of the Algerian plants. The flowers are of a deeper blue-purple, but for some reason the plant declines to flourish here. *W. R. Dykes, Charterhouse, Godalming.*

Fig. 19.—Iris unguicularis (syn. stylosa).

TREES AND SHRUBS.

ARBUTUS UNEDO AT AMPTHILL PARK, BEDFORDSHIRE.

Believing the following measurements to be unusual for a tree of Arbutus Unedo, I give them for the interest of readers of the *Gardeners' Chronicle* in general, while they may be of particular value to those recording remarkable specimens of tree-growth.

At about one foot from the ground level the circumference is 10 feet 6 inches, but immediately above this point the tree branches

into seven distinct stems, three large and four small. The circumference of these main branches at one yard from the ground is: 55½ inches, 50 inches, 35 inches, 16½ inches, 13 inches, 7½ inches, and 5½ inches respectively. The height of the tree is from 30 feet to 35 feet, and it has a spread of branches of 8 to 10 yards.

The evidence is clear that the whole tree has developed as a ground shoot or side growth from a previously existing tree, as a portion of the parent is still attached on one side, close to the ground, and is over 2 feet round.

Last year the largest branch was in danger of being badly damaged by a fall of snow, but we were fortunate in placing a strong prop under it before it was too late.

Perhaps someone interested in the dimensions of the growth of trees will say whether the above is a record for the Strawberry tree. The specimen is in the pleasure grounds here, which are, I believe, of very considerable age. *C. Turner, Ampthill Park Gardens.*

ORCHID NOTES AND GLEANINGS.

THE LATE JULES HYE DE CROM.

At the meeting of the Orchid Committee of the Royal Horticultural Society on January 14, the chairman, Sir Jeremiah Colman, Bart., read a letter, dated October 26, 1918, from Mme. Jules Hye de Crom, thanking the committee for the letter of condolence sent on February 11, 1915, which she had only then received, all letters having been detained by the Germans.

Mme. Hye de Crom remarked on the pleasure taken by the late M. Jules Hye de Crom in visiting and taking part in the exhibitions of the Royal Horticultural Society. After considerable difficulty with the enemy, which affected his nervous temperament, the end came suddenly from heart trouble.

It is probable that his collection of Orchids will be disposed of.

ODONTOGLOSSUM HUMEANUM.

A five-flowered inflorescence of the best form of this distinct natural hybrid between Odontoglossum Rossii majus and Odontoglossum cordatum we have seen is sent by Pantia Ralli, Esq., Ashtead Park, Surrey. The variety was first described in the *Gardeners' Chronicle*, 1876, p. 170.

The very attractive flowers are intermediate between the parents, O. Rossii majus predominating in the form of the lip and the disposal of the blotching on the petals, while the keeled sepals, with yellow ground, densely spotted with brownish red, resemble those of O. cordatum, save that they are larger. The

FIG. 20. ONION THE URN.
(See p. 50.)

petals are Primrose-yellow, with a cluster of red-brown blotches at the base; the lip is white, with a yellowish shade and yellow crest.

O. aspersum (Rossii × maculatum) appears sometimes in gardens, as O. Humeanum; its flowers, however, are not so large or pretty as those of O. Humeanum.

HYBRID ORCHIDS.

(Continued from p. 246, Vol. LXIV.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Lloyd George	B.-C. Marguerite Fournier × C. Lord Rothschild	H. T. Pitt, Esq.
Cattleya Avice	Heloise × Dowiana aurea	Sir Geo. L. Holford.

Sophro-Laelio-Cattleya Ruth	S.-L.-C. Marathon × S.-C. Doris	Flory and Black.

The Week's Work.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Lt.-Col. Sir G. L. Holford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Lycaste.—Plants of Lycaste are pushing forth their flowers, and an increased quantity of water at the roots will be needed to assist in their development. After the flowering period reduce the amount of water, and continue to do so until the plants start into growth again.

Cymbidium.—Cymbidiums have attained great favour since the introduction of the fine species C. insigne (syn. Sanderi), the parent of numerous grand hybrids now in cultivation, and in many establishments a house is set apart for their cultivation. The earliest flowers are opening, and, with a fair stock of plants, a succession of bloom may be maintained for the next three months. Thus the Cymbidium is one of the most useful of Orchids either for home decoration or exhibition; the spikes are very stately in appearance, and the individual flowers keep fresh for a long time. Cymbidiums thrive and flower best in a house having an ordinary greenhouse temperature, and, grown in cool treatment, no Orchids give less trouble. The spikes develop at the base of the newly-formed pseudo-bulbs after their completion in late autumn or early winter. They take a long time to come to perfection, and are a considerable drain upon the resources of the plant, therefore the roots should be kept fairly moist at this season. I do not advise the use of concentrated fertilisers in the cultivation of these plants, although some growers use them in solution rather freely while the flower-spikes are forming, but I question if much lasting good accrues from the practice. The use of stimulants may cause the spikes to lengthen, but it is not good for the roots. A substantial compost and clear water have, with me, been sufficient to obtain excellent results. It sometimes happens, when fine spikes are produced, the buds turn yellow and drop in considerable numbers. As a rule this is a sign of a bad condition at the roots, and the trouble seldom occurs when the plants receive cool treatment and no manure. A small brown scale insect sometimes attacks the plants, clinging with great tenacity and increasing rapidly. A careful watch should be kept for these insects, and if any are found on the plants they should be destroyed with as little delay as possible. After the plants have ceased to flower, and until they commence to grow again, water should be afforded sparingly. At the same time guard against drought, which would cause the roots and foliage to suffer injury.

THE HARDY FRUIT GARDEN.

By James E. Hathaway, Gardener to John Brennand, Esq., Baldersby Park, Thirsk, Yorkshire.

Cherries. — Take advantage of favourable weather to prune and nail Morello Cherries. As the fruits are produced on the shoots of the previous year, as much of the old wood as can be replaced by healthy young shoots should be cut away, and all weak growth cut out. The shoots may be trained rather closer than those of most other fruits, say, about 3 inches apart. It is a good plan to thin the shoots a little in summer, as this procedure obviates severe pruning in winter. The best method of training the Morello Cherry is in fan shape. The young shoots of May Duke and Bigarreau varieties should be shortened to about 3 or 4 inches to form spurs, but if summer pruning was carried out very little pruning will be needed now, simply shortening the growths to strong, plump eyes. If the trees are making gross growth and inclined to gumming, they should be root pruned, but this operation should be done in the autumn. Cherries thrive in rich soil for a long time without much manure, but trees in poor soils need a top-dressing of rich compost or farmyard dung, which may be applied now, first pricking up the surface of the soil lightly with a fork. Lime may be ap-

plied occasionally as a top-dressing where the soil is deficient in calcium. The following mixture of artificial manures may be used now, but not after February:—Bone meal, 2 cwt.; sulphate of lime, 4 cwt.; sulphate of potash, ½ cwt.; chloride of soda, ¼ cwt.; sulphate of magnesia, 28 lbs. per acre. Bone meal alone is very useful.

Newly Planted Fruit Trees.—The roots of newly planted fruit trees should receive protection from the frost: a mixture of litter and leaves forms a suitable material to use. The trees should be firmly staked, care being taken to prevent the bark from getting damaged. Where straps are not used for securing the trees, it is a good plan to protect the stems with a piece of old rubber, or canvas, hose pipe. In the case of standard trees it is best to use two stakes, one on either side.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

French Beans.—To maintain a regular supply of French Beans sow seeds at intervals of a fortnight. At this dull season good results are obtained by sowing six seeds in a 4-inch pot. The plants will grow more freely and make stronger specimens in the small amount of soil contained in these pots than when larger receptacles are used. Transfer them later to 7- and 8-inch pots, using a compost consisting of equal parts loam, leaf-mould and manure from a spent Mushroom-bed. Warm the soil thoroughly before using it for potting. Grow the plants in a warm, moist atmosphere, and top-dress them weekly. Early Forcing and Superlative are good forcing varieties, with Ne Plus Ultra and Magnum Bonum for later supplies.

Mushrooms.—Where a supply of fresh horse-manure is obtainable Mushroom-beds may be made at intervals to maintain a regular supply. If the manure is not forthcoming in good quantities, small beds should be made more frequently still, as, if the material is not collected almost at the same time for preparation, much of the value of the manure will be lost. Turn the heap every two days to allow the excessive heat and gases of fermentation to escape. When the temperature of the manure has fallen to 80°-85° make up the beds, and spawn them when the temperature is 78°.

Jerusalem Artichokes.—Lift the tubers of last year's crop of Jerusalem Artichokes when the weather is favourable, placing the large specimens under a wall facing north and covering them with sand or finely sifted ashes until required for use. If it is intended to grow these Artichokes on the same plot again dig the ground deeply or trench it, adding decayed manure or old vegetable soil. Plant medium-sized tubers in rows made 2 feet apart, and allow a space of 1 foot from set to set.

Seakale.—The bulk of Seakale crowns intended for forcing purposes should by now have been dug up and laid in sifted ashes in a position facing north, till they are required for forcing. The roots will readily respond to a little extra warmth when this transference takes place, having been kept in check in the cold, sunless position they have temporarily occupied. The thongs, or roots, taken from the crowns should be prepared without delay. It is not necessary to grow the crowns for two years if the crop is intended for home consumption only. By preparing the roots now the thongs will make strong, stocky growths by April, which is the time for planting them. In preparing the "sets" choose the strongest and cleanest roots, discarding any that show black rot, and burn them. Make the sets 6 or 7 inches in length, with the crown end cut squarely and the base obliquely, or slantways; this plan will prevent confusion as to which is the growing end. Tie the thongs in bundles of thirty to fifty, according to their size, and place them in boxes about 8 inches in depth, and work finely-sifted soil amongst them. Water them freely and stand the box containing them in a greenhouse or vinery. When the crowns are well formed place them in cold frames and ventilate freely on all favourable occasions, finally removing the lights entirely preparatory to planting them out-of-doors.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Orchard House.—All preparations for starting orchard house trees should be completed forthwith. If separate compartments or houses are available so much the better, but, failing this convenience, the early varieties of Peach, Nectarine, Plum, Cherry, Pear and Apple should be placed at the warmest end of the house. High temperature in mild weather should be prevented by admitting plenty of air. Fire-heat should be dispensed with as much as possible, only sufficient being used to prevent the temperature falling below 40° during severe weather. The trees may be syringed on bright days, but an excess of atmospheric moisture, especially during dull, cold weather, is harmful. All kinds of stone fruits do well in pots when carefully managed, and by forcing a batch of the earliest varieties the closing of permanent houses may, if desired, be deferred to a later date.

Vines in Flower.—The earliest varieties of Grapes should be grown in a night temperature of 60° to 65° as they come into flower, with a moderate rise during the day. With the exception of one liberal damping late in the afternoon, all syringing and damping should cease. To assist pollination tap the rods smartly twice a day to distribute the pollen. Shy-setting varieties should be pollinated by means of a camel-hair or light feather brush, using pollen of Black Hamburgh, if obtainable. As soon as a good set is obtained reduce the number of the bunches according to the vigour of the Vine. Thin the berries as soon as they are the size of Sweet Pea seeds. If the Vines are in pots, feeding should now be resorted to, but very mildly at first. Watch the bottom heat, and add fresh fermenting material as soon as the old begins to lose heat.

Mid-Season Vines.—The Vines which are intended to supply mid-season Grapes should be started now. Growth must not be unduly hastened in the early stages of forcing. A temperature of 45° to 50° at night, and 55° to 60° by day, should be maintained, but there should not be a rigid adherence to a definite degree, as a higher or lower temperature should be allowed according to the weather. Syringe the Vines once on each bright day, and damp the paths and borders when necessary to maintain a moderately humid atmosphere. Air should be freely admitted whenever it is possible to do so under favourable conditions. The borders should be examined, and if on the dry side let them be well soaked with tepid water. Now is a suitable time to start a Muscat-house for an early autumn supply, as by the time the Vines come into flower the weather will be favourable for securing a good set of fruit.

PLANTS UNDER GLASS

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

Roses in Pots.—Plants that were pruned, repotted, and plunged in a bed of leaves in a cold frame, last November, have started into growth, and may be brought into a pit or house, preferably a low-roofed structure, and placed near the roof-glass. Only a little fire-heat is required to maintain a mean temperature of 50° to 55°. In admitting air guard against cold draughts, which would favour attacks of mildew. Syringing the plants in the mornings on frequent occasions with weak, soapy water is a preventive of mildew, and also keeps the foliage clear of insect pests. As the plants develop in growth give frequent waterings with a weak solution of sulphate of ammonia, and retain only one flower on each shoot. Climbing Tea and Noisette Roses, planted in greenhouses or conservatories, will produce early flowers without the use of much fire-heat. For a supply of early flowers the plants are most successfully planted in a restricted root-space, and the shoots trained near the roof-glass. Let these plants have similar treatment to that advised above in respect to manuring and methods of combatting mildew and insect pests.

Herbaceous Calceolaria. — The florist's Calceolaria is one of the best subjects for the decoration of the cool greenhouse. Plants wintered in 4- or 5-inch pots should be shifted into 7-inch pots, in which they will flower. The soil should consist of a mixture of loam, leaf-mould and sand, with a little plant-fertiliser added. Guard against over-watering until the roots have grown freely in the soil. Place the plants near the roof-glass in a cool, airy house, using fire-heat only to keep out frost. Green fly is a great pest of the Calceolaria, and the house should be fumigated occasionally.

Seed Sowing.—Seed of various plants that are useful for flowering under glass require to be sown in February. Some, such as those of Begonia, are so small that the greatest care is required in sowing them. Use shallow pans containing plenty of drainage material. The soil should be of a light texture and mixed with leaf-mould and sharp sand, passed through a fine sieve. Finish the filling of the pans with a smooth, level surface of very fine soil and immerse them in water to thoroughly soak the soil before sowing the seeds. Follow this method of watering until the seedlings are ready to be transplanted. Very minute seeds require no covering of soil; simply press them lightly into the surface. Place sheets of glass over the seed-pans, and a paper covering over the glass. Germinate the seeds in a temperature between 60° and 70°, and when the seedlings appear remove the coverings. Place the pans on the shelf near the glass in a warm house, and shade the plants from direct sunshine; larger seeds should have a light covering of soil, which should be lightly pressed down.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Azalea Ghent and Others. — Few hardy flowering plants give a more brilliant display of bloom or are more conspicuous in the pleasure grounds when planted in masses, or in suitable places in borders, than Ghent and other Azaleas. If the planting of new beds of Azaleas is contemplated this coming spring, the work of preparing the soil should be hastened in suitable weather and completed before other matters become more urgent and pressing. Efficient soil drainage is essential to success with these shrubs. The compost in which they are planted should be sweet and somewhat lumpy, consisting of loam of a rather sandy texture, rough peat, leaf-mould, and plenty of grit, thoroughly mixed and trampled firmly.

Rhododendrons may be successfully planted very late in the spring. The commoner varieties thrive well in almost any ordinary soil, provided it is well broken up and the drainage perfect. The choicer sorts should be given good positions and the soil and stations carefully prepared. Whether the plants are to be grown in beds, dotted in threes, or as single specimens, much of the soil, if of an unsuitable nature, should be removed, and a compost consisting of fibrous loam, peat, leaf-mould, grit, and a little thoroughly decomposed manure, substituted. The soil in which the plants are set should be raised several inches above the surrounding level.

Plants Growing on Walls.—The mild weather has caused many plants growing on walls to make very early growth, and any pruning and regulating of the shoots and branches may be done in favourable weather. See that all the main supports are sound and in good order, to prevent damage by gales. Prune, more or less, all plants that are becoming crowded. Clematis should be attended to before the growths are too forward, otherwise much harm may be done in disentangling any of the last season growth.

Lily of the Valley.—In order to obtain good spikes of Lily of the Valley roots should be planted annually in well-manured soil, in a situation facing east or west. To obtain large spikes plant evenly-sized crowns 2 or 3 inches apart, keep the beds free from weeds, and give the roots an occasional watering with liquid manure during the growing season. When lifting the plants from beds, keep the flowering crowns separate, pot them, and flower them in gentle warmth. Re-plant the next strongest in the beds or borders.

APPOINTMENTS FOR FEBRUARY.

MONDAY, FEBRUARY 3—
Nat. Chrys. Soc. ann. meet. at Essex Hall, Essex Street, Strand, at 7 p.m.

TUESDAY, FEBRUARY 4—
Bolton Hort. and Chrys. Soc. meet.

THURSDAY, FEBRUARY 6—
Royal Gardeners' Orphan Fund ann. meet. and election of orphans at Simpson's Restaurant, Strand, at 3 p.m. Manchester and N. of England Orchid Soc. meet.

FRIDAY, FEBRUARY 7—
Lea Valley and District Nurserymen's and Growers' Assoc. ann. dinner at Great Eastern Hotel, Liverpool Street, at 6 p.m.

MONDAY, FEBRUARY 10—
United Hort. Ben. and Prov. Soc. Com. meet. Bath Gard. Soc. meet.

TUESDAY, FEBRUARY 11—
Roy. Hort. Soc. ann. meet.; Coms. meet. at 12 p.m. Hort. Club ann. meet. and dinner at 2, Whitehall Court, Whitehall.

WEDNESDAY, FEBRUARY 12—
Wargrave Gard. Soc. meet.

FRIDAY, FEBRUARY 14—
Richmond Allotment Association, meet. and lecture, 8 p.m.

MONDAY, FEBRUARY 17—
Nat. Chrys. Soc. Executive Com. meet. at 35, Wellington Street, Covent Garden, W.C., at 6 p.m.

THURSDAY, FEBRUARY 20—
Manchester and N. of England Orchid Soc. meet. Brighton Hort. Soc. meet.

THURSDAY, FEBRUARY 25—
Roy. Hort. Soc. Coms. meet: Lecture by Capt. Arthur Hill, M.A., at 3 p.m., on "The Care of Our Soldiers' Graves."

WEDNESDAY, FEBRUARY 26—
Wargrave Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.5°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, January 27, 10 a.m.: Bar. 30; temp. 39°. Weather—Dull.

SALES FOR THE ENSUING WEEK.

MONDAY and TUESDAY—
Clearance Sale of Ware's celebrated collection of Begonias, Dahlias, Herbaceous Plants, Vases, Office Furniture, &c., at Ware's Nurseries, Feltham, by Protheroe & Morris at 12 o'clock.

WEDNESDAY—
Sale of Rose, Fruit Trees, Plants, and Bulbs at 67-68, Cheapside, by Protheroe & Morris, at 1 o'clock.

The Soil Solution. American investigators have been actively engaged during the last few years in searching for what may be called a chemical index of soil fertility. By common consent chemical analysis of a soil is to be regarded at best as but a rough indication of its fertility.

The guiding idea adopted by many modern investigators may be expressed thus. It is not the chemical constitution of the soil which directly determines fertility, but rather fertility is determined by the composition of the soil solution—that is, the fluid consisting of water and dissolved mineral and other substances which occur in the soil. From this soil solution, films of which surround and adhere to the soil particles, the roots of plants draw their supplies of "food": for inasmuch as plants may only absorb substances which exist in the soil in a state of solution, the insoluble materials in the soil are of no *direct* account as contributors to soil fertility; therefore, it is the substances dissolved in the soil solution which determine the fertility of the soil. On this view the chemical composition of the soil solution is the index of soil fertility, wherefore it becomes important to discover a method of extracting from the soil a true sample of the soil solution. This problem, it is claimed, has been solved by displacing the soil solution by oil. Since the soil solution is held with great tenacity by the particles to which it adheres, it is necessary to push it out by driving in the oil under considerable pressure. This oil pressure method of extracting the soil solution is now being employed for the purpose not only of investigating the natural composition of the soil solution, but also of determining the effect produced on the soil solution by the addition of fertilisers. For example, before the nitrogen in such a manure as dried blood may be made use of by plants the organic compounds in which it occurs must first be operated on by soil bacteria, which disengage the nitrogen from these organic compounds and liberate it as ammonia. So in turn other bacteria oxidize the ammonia and produce nitrates, in which form the nitrogen contained in the fertiliser may be absorbed by the roots.

By obtaining samples of soil solution at successive intervals after the application of a fertiliser it is possible to infer the rate of change of organic nitrogen to nitrate in a given soil.

As an illustration, the results of using this method for comparing the rate of action of different fertilisers, dried blood, cotton seed meal, etc., may be given. In the case of dried blood the production of ammonia as revealed by the composition of the soil solution was at its maximum two weeks after its application, and was completed within four weeks; nitrification began within two weeks of the original application of the fertiliser, and proceeded at a great rate during the third week. In the case of cotton seed meal, ammonification followed a slower course. It began about four weeks after application, reached a maximum at twelve weeks, and then fell off gradually; but even at the end of twenty weeks ammonia was still being produced in the soil manured with cotton seed meal at four times the rate at which it was being found in a similar but unmanured sample of the soil.*

The illustration is given primarily with the object of showing that the new method appears to be likely to prove of value in practice. For instance, a grower whose soil is a stiffish loam may discover that such a manure as dried blood is of great value as a stimulant to early growth. Another grower whose soil is much lighter, learning of this might well decide to try the effect of this manure on his soil. Owing to the much greater rate of ammonification and nitrification which, as shown by the oil pressure method, occurs on lighter soils, he would probably discover that two successive light dressings are more economical and efficacious than one larger dressing. In any case, the oil-pressure method of extracting soil solutions, and thereby providing material for a chemical index of soil fertility, is one which will be watched with interest not only by students of soil chemistry, but also by plant growers.

* Bull. No. 39, Michigan Agric. College, Sept., 1917

Royal Gardeners' Orphan Fund. — The annual meeting of the Royal Gardeners' Orphan Fund will be held at Simpson's Restaurant, 100, Strand, London, W.C., on Thursday, February 6, at 3 p.m., for the purpose of receiving the report of the committee and statement of accounts for the past year; to elect officers for the ensuing year; to elect by resolution eleven children to the benefits of the Fund; and to transact such other business as may arise

Seeds for 1919.—A census of stocks and prospective supplies of agricultural and garden seeds in England and Wales recently taken by the Board of Agriculture indicates that, with a few relatively unimportant exceptions, ample quantities are available to meet the estimated demand for sowing this spring. The need for continued economy in the use of seeds should not, however, be overlooked. Allotment-holders and other growers should calculate their seed requirements with care in order to prevent waste. Purchasers are reminded that under the Testing of Seeds Order seedsmen are required to disclose certain essential facts regarding the quality of the seeds they sell. Standards of germination and purity are specified in the Order and small packets of vegetable seed falling below these standards must be so declared. An implied guarantee that the seeds are up to or above the standards specified in the Order is therefore given with all packets of vegetable seeds affected by the Order unless the seller makes a declaration to the contrary at the time of sale. The Official Seed Testing Station for England and Wales, 72, Victoria Street, London, S.W. 1, is prepared to test seed for allotment-holders and others, who intend to use the seed for their own sowing, at the rate of 3d. per sample.

Paris Spring Show.—A show will be held in Paris from June 5 to June 9 next. It will include exhibits of all kinds of garden produce and horticultural sundries.

Chairman of the Wisley Development Committee.—The Rev. W. WILKS writes: "It is regretted that in the Royal Horticultural Society's 'Book of Arrangements for 1919,' on p. 22, the name of the chairman of the Wisley Development Committee is incorrectly stated. It should read: Mr. H. B. MAY, V.M.H., and not Sir HARRY VEITCH, who resigned the chairmanship in July last."

National Chrysanthemum Society. — The annual general meeting of members of the National Chrysanthemum Society will be held at Essex Hall, Essex Street, Strand, London, W.C., on Monday, February 3, 1919, at 7 p.m. The report of the Executive Committee and the financial statement for 1918 will be presented, the officers and one-third of the Committee elected for 1919, and such other business transacted as pertains to an annual meeting. The president, Sir ALBERT ROLLIT, LL.D., D.C.L., V.M.H., will preside.

French Horticultural War Relief Fund.—The National Horticultural Society of France has opened a subscription list amongst its members to form a fund to assist all those persons who, from a horticultural point of view, have been victims of the German invasion and have suffered damage from acts of war. Subscriptions should be sent to the Treasurer of the Society, 84, Rue de Grenelle, Paris.

Sugar for Bee-Keepers.—Bee-keepers will be interested in the arrangement made by the Food Production Department and the Royal Commission on Sugar Supply by which sugar for bees will be available for spring feeding. It should be noted, however, that this distribution will take place only to bee-keepers who have registered with the Horticultural Sub-Committee of their county. Each registered bee-keeper will obtain from the Horticultural Sub-Committee a certificate which, on being presented to the local Food Control Committee, will be exchanged for

"Where Capital & Labour Meet"

at the Employment Exchange

In the case of both Master and Man—the road to mutual satisfaction is the Employment Exchange. There is an Employment Exchange for every important district in the country, supervised by a joint committee of employers and workpeople.

Both Employers and Men are urged to realise—

1. That the nearest Employment Exchange is the nearest way to a good job for a man.
2. It is the nearest way to getting a good workman that any employer can take.
3. The Employment Exchange can supply the employer with a man who has fought for him. It is only fair that he should be given the chance to work for you. He helped to forge victory. His now the just claim to enjoy its fruits.

The Employment Exchange is the common meeting ground for master and man. The Government bring the twain together.

If you want a good man—if you want a good job—go to your nearest Employment Exchange and get one!

CLIBRANS (By Appointment To H.M. The King) ALTRINCHAM.

BUNYARD'S VINES.

We can offer the following varieties in extra fine fruiting canes at 30/- each, planting canes at 21/- and 15/- each:—

BLACK HAMBRO, LADY DOWNES, BLACK ALICANTE, MUSCAT OF ALEXANDRIA, APPLEY TOWERS, FOSTER'S SEEDLING, BUCKLAND SWEETWATER, MUSCAT HAMBRO, MRS. PRICE, PRINCESS OF WALES.

Our Vines are well known for their well ripened short fruited wood.

a sugar voucher available for the purchase of sugar from any retail or wholesale dealer. To date 6,469 bee-keepers, with 23,642 stocks in frame hives and 3,107 stocks in skeps, have registered under the F.P.D. scheme.

Brighton and Hove Horticultural Society's Meetings in 1919.—The Brighton Society has arranged an excellent series of meetings for the present year. The programme differs somewhat from previous years, as the wider scope of the Society—now the Brighton, Hove, and Sussex Horticultural and Food Production Society—allows a wider range of subjects. The dates of meetings and lectures, as originally sent in and published in our Almanac, have been amended, and are now as follows:—January 30, Annual Meeting; February 20, "Talks on Hardy Fruit Trees," by Mr. Frank Woollard; March 20, "Vegetables for Allotment-holders," by Mr. G. Chandler, to be followed by a concert arranged by Mr. G. A. Miles; April 17, "Seed Sowing and Transplanting," by Mr. Chas. Watts; May 22, "A Chat about Allotments," by Mr. W. Rushton; June 1, outing to Hollingbury Camp, and "Talks on Prehistoric Allotments," by Mr. Herbert S. Toms; June 19, "Forests of Sussex, Wood Industries and Trees," by Miss H. E. Ansell; September 18, "History of Preston, and Short Talks on Popular Prestonians and Horticulturists," by Mr. A. J. Easton (hon. secretary); November 20, "Landscape Gardening, Rock Gardens and Flower Borders," by Mr. E. Scaplehorn. The Society will also hold an exhibition in October and a Summer Outing in July, the dates and details of which will be arranged later.

Soldiers' Graves in France.—At the meeting of the Linnean Society of London, held on the 16th ult., an account was given by Captain A. W. Hill of the horticultural work that had been carried out in the military cemeteries in France since 1916, when such work first became possible; reference was also made to the cemeteries in the Italian and other theatres of war. It is intended to make the cemeteries, as far as possible, smooth, well-kept grass-lawns, surrounded by hedges of Thorn, Beech, or Hornbeam, with groups, avenues, or pole-hedges of trees, such as Siberian Crabs, Limes, Hornbeams and Willows, and to plant on the graves Rose bushes, Iris, and other dwarf carpeting-plants. Steps are being taken as far as possible to mark the cemeteries where Canadian, Australian, New Zealand, Indian, and other overseas soldiers lie buried with plants native to the countries whence they came to the defence of the Empire. Allusion was made to the problems which have to be faced in the matter of soil and site, which often render successful gardening work very difficult. Some of the cemeteries are in very sandy places, others in chalk, whilst a number are in the fenland of the Belgian border. The results so far obtained have proved that, given proper care, whatever the soil may be, a good turf can be formed in Northern France. In the cemeteries where permanent planting is not yet possible good results have been obtained by sowing annuals, either according to a well-arranged colour-scheme, or in mixture, and the effect in summer has been quite beautiful and much appreciated by our soldiers in the field. Bulbs have been extensively planted. Nurseries have been established for the supply of plants, trees, and shrubs to the numerous cemeteries. A series of slides was shown of cemeteries in various parts of France, some situated in old orchards, some in sandy districts, and others in the open country, and from them a good idea was obtained of the care and labour bestowed by the officers and gardening N.C.O.s and privates attached to the Imperial War Graves Commission in France.

National Sweet Pea Society's Programme for 1919.—The National Sweet Pea Society will hold an exhibition on July 4, and propose to hold a dinner and conversazione at the close of the show, and an outing to some seed-growing centre on the day after the show. The Society's Scottish Cup is offered for competition at Aberdeen, and a strong effort is being made to obtain new members and the return of those who have lapsed during the period of the war.

The Chamber of Horticulture.—During the past few days the British Florists' Federation, the National Sweet Pea Society, and the British Carnation Society, have decided to become attached to the Chamber of Horticulture.

Fig. 21.—Anemone patens var. ochroleuca: flowers sulphur-yellow.

THE ALPINE GARDEN.

ANEMONE PATENS VAR. OCHROLEUCA

Anemone patens is a very widespread species, for it grows wild in Europe, Siberia, and North America. Growing naturally under such diverse conditions, it varies considerably, and there are several named varieties in cultivation. The typical plant has tufts of palmately-divided leaves on long petioles, and large, rich purple, silky-haired flowers. This form is found both in Europe and Siberia. Another variety, A. p. Wolfgangiana, which is found in Russia and Northern Asia, differs in having more deeply laciniated and longer, narrower leaf segments. The North American form is known as var. Nuttalliana and has large, pale-lavender coloured flowers.

The variety illustrated in fig. 21 was raised from seeds received from Petrograd in 1915 under the name of Anemone patens var. lutea. The same plant, however, was figured in the *Botanical Magazine*, t. 1,994, just a century ago, under the name of A. p. var. ochroleuca, which name must therefore have precedence. This yellow flowered form is met with occasionally both in Russia and in Siberia, but does not appear to be so common as the purple-flowered type. The variety is readily raised from seeds, and the plants flower in their second year. Deep, well-drained, loamy soils are suitable to this perennial plant, and it appears to do best in situations sheltered by low-growing shrubs.

This species belongs to the section of the genus Anemone known as the Pulsatilla group, all the members of which have heads of long, silky-tailed fruits which are very ornamental. *W. I.*

MEDICINAL PLANTS.*

(*Concluded from p. 45.*)

Having made a hurried review of the general aspect of the subject, it is necessary to briefly consider the drug plants themselves. To simplify the question, it is best to adopt some kind of classification, and for this purpose they may be conveniently divided into three arbitrary divisions—(1) those produced by horticultural cultivation; (2) those produced by agricultural cultivation; (3) wild plants collected from the countryside. Group three is obviously outside the scope of this paper and will therefore not be considered. The first and second groups are interchangeable in certain aspects—that is to say, some plants can be cultivated either way, just as Potatos are. But there is a certain number which can only be profitably and successfully grown in large numbers, as the produce is required only on a large scale. The plants falling into the second group would comprise such herbs as Lavender, Peppermint, Fennel and Caraway, which must be supplied in large quantities to meet the requirements of the market, and it would be just as futile to attempt to grow them profitably on a small scale as it would be to grow cereals in a garden bed. The plants which lend themselves to cultivation on a smaller scale, and which would come under the category of horticulture, are Aconite, Colchicum, Belladonna, Chamomile, Foxglove, Henbane, Roses, and Valerian. It is not within the scope of this paper to deal with the strictly technical side of this subject, because, after all, the cultivation of these plants is practically on the same lines as for all herbaceous and annual plants. To obtain the best results, good cultivation and deep, rich soil are essential. Keep the land free from weeds, watch the calendar, and harvest at the correct season. No hard and fast rules should be laid down, for the best results can only be obtained by trial.

Aconite is only grown for its tuberous roots.

* By R. Glode Guyer, Edinburgh. Reprinted from the *Transactions of the Scottish Horticultural Association*, Vol. III., Part 2.

Aconitum Napellus is the species demanded. The roots are dug up in the late autumn, the new offshoot roots of the mother plant are divided and replanted for the next season's stock, and the bulk of the root is kept for drying.

Belladonna is raised from seed, which is best sown in frames or in boxes under glass, and pricked out into the permanent growing beds when strong enough to stand transplanting. Belladonna forms a large plant, and is a strong grower, therefore the seedlings should be planted out in rows about 3 feet apart, and 2 feet between the plants in the rows. The upper annual growth should be cut down when the plant has flowered, in August or September, and the leaves should be cut off and dried, when they are ready for market. The plants should be protected against frost by a covering of dry litter or Bracken. In the second year it is possible, if the growing season is a good one, to obtain two crops of leaves, one in July and the other about September. The roots are then dug up and dried for the market, though they may be kept for another year, but after the third year they are generally coarse and heavy, and are not considered to be a good marketable article. Owing to this destruction of stock in the second or third year, it is incumbent upon the grower to raise a new crop of plants annually to replace those dug up for their roots, and this succession must be carefully maintained.

Chamomiles.—The dried, half-expanded flowers of Anthemis nobilis are in great request, and it is the double flowers which are demanded to meet market requirements. At one time these were grown in Scotland for this purpose, and Scottish Chamomiles always commanded a higher price than those imported. The supply has dwindled away because of the Continental competition, and also chiefly because no dependence could be placed upon regularity of supply. In connection with this it is interesting to note that Queen Victoria's mother, the Duchess of Kent, required a supply annually for her personal use, and this she obtained from Aberdeenshire, where, it appears, the cottagers used to grow the plants, the harvested flowers being collected and sold in bulk and the proceeds distributed according to the supply obtained.

Colchicum, or autumn Crocus, is always in great demand, and for many years past the demand has exceeded the supply. Propagation is the same as for all corm plants. Colchicum demands a warm, moist soil, and that is why it naturally always prefers the riverside meadows. The corms, when they are dug up, are sliced and then dried.

Foxglove.—It may appear absurd to suggest the cultivation of this very plentiful wild plant, but the reason is not far to seek. The collection and transport of the plant in its wild state is generally so costly that it becomes an unprofitable undertaking, but Foxgloves can be readily cultivated in spare ground, and if closely planted, with alleys between the rows to admit the free passage of the collectors, they become a profitable crop, as they require but little attention. To be commercially successful the plantations must be of such a size that a good yield of leaves can be gathered, say a minimum of 2 cwt. of the dry marketable product, and as these leaves lose about 85 to 90 per cent. of their weight in drying, the moist weight of this quantity represents from 1 to 1½ ton.

Henbane is a curiously fickle plant to cultivate. Germination is remarkably slow and uncertain, and it is also impossible to lay down any rules or guiding lines about soils, as it will grow freely in one field and refuse to grow in another within a distance of a few hundred yards. The question whether Henbane is an annual or a biennial is a botanical problem which requires solution. From a single sowing some plants developed into the so-called annual variety, blossoming and dying away, while others threw up a rosette of leaves from which the main flower stalk was produced the next season. As previously mentioned, Henbane has a varied taste for soil and environment, and it is on account of its cosmopolitan tastes that the cultivation is so difficult; but these difficulties are compensated for by the fact that there is almost always a shortage of supplies, and market prices invariably rule high. The flowering tops and leaves are the parts required in pharmacy.

Roses are valuable for their dried petals, and perhaps to a horticulturist this may be an attractive line as a by-product, especially to those who are extensive Rose growers. Correctly speaking, the petals demanded by the *British Pharmacopoeia* are those of Rosa centifolia, but commercially any of the rich deep red varieties are offered. Well-collected and preserved Rose petals always command a ready sale and a good price. The flowers must be cut when about half expanded, and not allowed to become fully blown. This is a very essential point, as the petals of a fully-blown Rose never yield a good richly-coloured product. Another point which must be borne in mind is that it is best when possible to collect them in dry weather, but where this is not feasible all moisture must be well shaken off before cutting, as moisture deteriorates the colour in the process of drying. They should be dried without heat, and in the shade.

Valerian.—The root of the ordinary wild Valerian (Valeriana officinalis) is required, and not, as so many think, that of the red Valerian (Centranthus ruber), which is valueless. This plant requires very little attention, and if cheap unskilled labour is employed a profitable harvest can generally be made. The roots are dug up in the fall of the year, washed and dried, when they are ready for the market, and the beds are then replanted for the next season.

This list is not a formidable one. Other medicinal plants might be included, but it embraces the most important ones which are most suitable for cultivation, and also those for which there is a constant and steady demand. There should be a good future for work of this kind, if systematically taken in hand, and the working result of the first two or three years is not to be taken as either conclusive or final. These years must be reckoned as experimental only, and if unprofitable the cause must be found out and eliminated, so that the work may be brought to a high pitch of excellency. Reason it out carefully, and do not abandon the work as useless and unremunerative on one or two years' returns. Bear in mind that if the Germans can make it pay, and make it pay handsomely, you should be able to do it here in Scotland. It is a matter of congratulation and encouragement that recently the Edinburgh and East of Scotland College of Agriculture appointed a committee to take up this matter, and with their co-operation and advice the cultivation of medicinal plants in Scotland bids fair to have a future, in which once again Scottish industry and Scottish enterprise will make another mark in the history of commerce.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Apple Edward VII. (see p. 21).—I endorse every word stated by Mr. Tubb as to the merits of Apple Edward VII. This variety is fast taking a leading position amongst the very best late-keeping Apples. It received the R.H.S. Award of Merit some years ago, and although the fruits have been submitted to the Fruit and Vegetable Committee since, for some unaccountable reason the variety has failed to receive the higher award it so richly deserves. We have grown trees at Madresfield Court amongst upwards of two hundred varieties in our trial orchard, and it has long ago secured top marks, consequently we have propagated and planted it extensively in the new orchards under the scheme in vogue on Earl Beauchamp's estate. The tree has a strong, healthy constitution, is a compact grower, with short, pointed growth, and forms abundant fruit spurs on all wood. The leaves are rather small and pointed. The variety makes a perfect bush, or standard, for planting in grass land. The fruit is smooth, yellow, and handsome, and keeps long in good condition, the flesh being of great density up to June and later. It is altogether a most desirable variety. The same remarks apply to Sandling Duchess, another grand late keeping variety. *William Crump, Madresfield Court, Malvern.*

Rosa Moyesii var. Fargesii (see p. 19).—In his interesting note in your issue of January 11 Mr. Rolfe discusses the Rose species Moyesii and Fargesii, and concludes that the two cannot be separated. I notice that he describes the colour of both as "deep crimson," but that hardly does justice to the colour, the charm of which it is difficult to discuss in words, the nuance being of the type of tint to which the title "old" is generally given. To me the colour suggests something characteristically Chinese, recalling the tints of the old embroideries of that country. There is certainly no other flower giving the same colour effect. I wonder whether your contributor can explain the occasional appearance at shows of a variety in which the flowers are of a disagreeable terra-cotta or Austrian Briar appearance? The description of R. Moyesii in more than one rosarian's catalogue suggests that this variety is fairly widespread, and this may account for the want of appreciation which seems to be shown of what is undoubtedly the most striking Rose novelty of this generation. It may be that the colour of the atrocity which often masquerades as Moyesii is due to some peculiarity of the cultural conditions (I have seen it as a pot plant only), but if the colour is constitutional let us give it a name which will serve as a danger-signal. *A. B. B.*

Rabbits and Fruit Trees (pp. 19 and 46).—The method of protecting fruit trees in Scandinavia from injury by hares might be adopted in this country where rabbits attack the bark of orchard trees in winter. Young Ash trees are cut down and placed in the outskirts of the orchard. One tree would be enough per acre, and supplies the bark the animals seem to need during the colder period of the year. *T. Ritz.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 28.—The meeting held on this date at the London Scottish Drill Hall, Buckingham Gate, was fairly well attended, considering the heavy snowstorm experienced during the previous night. Orchids, hardy plants, Primulas, and Nature Study exhibits provided a display of considerable extent and interest, but the Hall was so very cold that only those compelled to stay with their exhibits remained after a brief inspection.

The Floral Committee awarded five medals and one Award of Merit; the Orchid Committee granted two medals and one Award of Merit; and the Fruit and Vegetable Committee one medal and a First-class Certificate.

Under the aegis of the School Nature Study Union numerous Nature Study exhibits were staged, and would have greatly delighted youngsters who love Newts, Water Boatmen, Frogs, Moths, and Butterflies. Miss WYSS was responsible for the "animals," and the Misses PUGH, MACKIE and HILL contributed a large collection of twigs, to show colouring, branching, bud development, and fruits. Miss PAULSON showed lichens and soils of various colours and textures. Mr. UPFIELD sent photographs of natural objects, and from the Froebel Institute came clay models of birds, insects and barks, and handiwork done in connection with Nature work—for instance, there were golliwogs made of Chestnut burrs and nuts, and necklaces of Beech nuts and husks. Mr. POTTS had charge of the gardening section, where photographs of garden work were displayed, with wooden baskets, a seed-sower, Pea-protectors, and a large assortment of dibbers, few of which found favour with the practical men present.

Miss WILLMOTT contributed a large group of small branches of evergreen trees and shrubs, many of them carrying either cones, berries or flowers. No fewer than 130 species were repre-

sented, all from Warley Place Gardens and gathered in the snow!

Floral Committee.

Present: Messrs. H. B. May (in the chair), E. A. Bowles, W. J. Bean, Sydney Morris, R. C. Notcutt, John Green, J. F. McLeod, W. Cuthbertson, John Heal, Herbert Cowley, G. Reuthe, W. Howe, C. Dixon, E. H. Jenkins, Chas. E. Pearson, George Paul, and R. W. Wallace.

Award of Merit.

Primula malacoides The President.—A double form with the floral segments deeply notched and often pointed, so that the general effect is elegant. Like the type, the variety is very free-flowering, and the colour of the flowers is bright rosy lilac. Shown by Messrs. Jas. Carter and Co.

Groups.

Mr. G. W. Miller's Daffodils, Tulips, and coloured Primroses assisted to brighten the gloomy hall, and he also showed Snowdrops, pots of Iris reticulata, and Muscaris. (Bronze Flora Medal.) Varieties of Cyclamen Coum, Berberis hyemalis and Helleborus foetidus were attractive in a group of hardy plants staged by Mr. Reuthe.

Some beautiful branches of Eucalypti in bud and flower, and elegant pendulous sprays of Cytisus monosperma, all from the South of France, were displayed by Mr. R. F. Felton, and were greatly admired. (Bronze Flora Medal.) Market White Freesia, a new variety raised and shown by Messrs. Herbert Chapman, is a fine form, but it is not pure white, as most of the flowers have faint yellow markings.

In a group of hardy plants exhibited by Messrs. J. Piper and Sons, about six dozen pans of hardy Cyclamen were the chief feature; those of C. Coum was most numerous and C. Atkinsii the most richly coloured. (Bronze Flora Medal.) Chinese and Stellata Primulas, with P. malacoides, were exhibited largely by R. L. Mond, Esq. (gr. Mr. C. Hall), Coombe Bank, Sevenoaks. The Primulas were backed by Epacris, and made a large and attractive group. (Silver Flora Medal.) Messrs. J. Carter and Co. submitted the double Primula malacoides The President and a richly coloured form named King Albert. (Bronze Banksian Medal.)

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), William Bolton, Frederick J. Hanbury, R. G. Thwaites, Pantia Ralli, Chas. H. Curtis, S. W. Flory, W. J. Kaye, C. J. Lucas, R. Brooman-White, and J. E. Shill.

AWARDS.

Award of Merit.

Odontoglossum ardentissimum Reine Blanche (*crispum xanthotes* × *Pescatorei album*), from Dr. Craven Moore, Victoria Park, Manchester. —A very beautiful pure white variety of perfect shape, the only colour consisting of a few light yellow blotches on the lip.

Groups.

Messrs. Armstrong and Brown, Tunbridge Wells, were awarded a Gold Medal for a group having a frontage of 35 feet, made up of about 100 excellent specimens of Cymbidiums, Odontoglossums, Odontiodas, and Calanthes. The centre was of Calanthe Wm. Murray, white with purple lip, and C. Florence, bright rose, with white eye; and at the back was a selection of Cymbidiums, among which was C. Moira var. Elatior (Tracyanum × Pauwelsii). This variety resembles a large C. Tracyanum, with light yellow ground striped and spotted with purplish red; the spike carried 13 flowers. Some fine seedling Odontoglossums and Odontiodas were also staged, the best novelties being Oda. Madeline var. Flamingo (orange-red on yellow ground); Odontoglossum Victory var. Marvel (a large, clear white flower, richly blotched with claret-red); and Odm. promerens Model, a perfectly-formed white flower with reddish-purple blotches on the inner two-thirds of the segments. Cirrhopetalum gracillianum and several other pretty species were also in the group.

Messrs. Charlesworth and Co., Haywards Heath, were awarded a Silver Flora Medal for a group of exceptionally fine Odontoglossum and other hybrids. The prettiest novelty was Odontoglossum Radiant (Dora × Alexandrae), two varieties of which were shown. The flowers are white, tinged with rose, and profusely spotted with purplish blotches of varying size.

Frederick J. Hanbury, Esq., Brockhurst, East Grinstead, showed a flower of his new Cypripedium Major Hanbury Carlile (Troilus Amy Moore × Lady Carlile), the largest and most refined of its section. The white dorsal sepal had a yellowish base and dark ruby-claret blotched lines, the rest of the flower being yellow tinged with purple and spotted on the lower halves of the petals. Mr. Hanbury also showed flowers of two other new hybrids.

Baron Bruno Schroder, The Dell, Englefield Green (gr. Mr. J. E. Shill), sent Laelio-Cattleya Schröderae, pure white with rich maroon lip; and Cypripedium Eurybiades Helmuth, well worthy of the fine varieties previously flowered from the batch.

Dr. Miguel Lacroze, Bryndir, Roehampton (Orchid grower, Miss Robertson), showed Cypripedium Isonzo var. Bryndir (Alcibiades × Mrs. Wm. Mostyn), a good flower, the white dorsal sepal of which is heavily blotched with dark purple, the rest of the segments being yellow with red-brown tinge and spotting.

Mrs. Norman Cookson, Oakwood, Wylam-on-Tyne, sent Cypripedium Oakwood Giant (Beeckmanni × Harold), a gigantic flower with white dorsal sepal having a greenish base and thin purple dotted lines, the broad petals and lip greenish, with purple flush and some spotting on the petals.

Messrs. J. and A. McBean, Cooksbridge, staged a small group, in which were varieties of Brasso-Cattleya Bianca, Cattleya Trianae alba, and C. General Pulteney (Octave Doin × Trianae), the latter an attractive flower of good shape and bright colour.

Messrs. Flory and Black, Slough, showed a selection of Sophronitis crosses and seedling Odontoglossums. Sophro-Cattleya Eva (S.-C. Saxa × C. Enid) is rose-coloured on a cream ground, prettily marked and veined. S.-C. Nerissa (S.-C. Saxa × Trianae Backhouseiana) has rose sepals and petals, with a reddish glow obtained from the Sophronitis. S.-L.-C. Iris (L.-C. Thyone × S.-C. Doris), a pretty yellow flower; Odontoglossum Portia (illustrissimum × Aglaon), and the fine new seedling Odontoglossum crispum Windsor, with rich purple blotching on a white ground, were also noted.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), W. Poupart, E. Beckett, W. Bates, F. Jordan, J. Basham, W. H. Divers, and H. S. Rivers.

First-class Certificate

Apple St. Cecilia.—This handsome and useful Apple, described and illustrated in *Gard. Chron.*, Feb. 2, 1918, now received the higher award. The Apple is finely flavoured, and Cox's Orange Pippin was one of its parents. Shown by Mr. J. Basham, Bassaleg, Monmouth.

A very fine display of bottled fruits and preserves was made by Lady Elizabeth Dawson, Canon Hill, Maidenhead. Gooseberries, Raspberries, Loganberries, Apricots, Peaches, Strawberries, Nectarines, Red, White, and Black Currants, and Mulberries were included, and all were clear and bright. Of preserves, the Mock Guava jelly made from young green Gooseberries, Tomato chutney, Crab-Apple jelly, and Barberry jelly, were the most important. (Silver-gilt Knightian Medal.)

Messrs. Whitelegge and Co. sent three Onions, named respectively Whitelegge's Excelsior, Kentish Keeper, and Cooper's Density; the first-named is a broad, solid Onion of good size and appearance. The varieties are to be sent to Wisley for trial.

LANGHOLM HORTICULTURAL.

At the recent annual meeting of the Langholm Horticultural Association, Dumfriesshire, it was decided to resume the annual show, which is to be held at Langholm on August 23. Mr. Jas. Cairns was appointed president of the Association; Mr. S. Hyslop, Lake House, vice-president; and Mr. G. W. Paterson hon. secretary and treasurer.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL MEETING.

January 23.—The seventy-ninth annual general meeting of subscribers to this Institution took place on the foregoing date at Simpson's Restaurant, 100, Strand. Sir Harry J. Veitch, chairman and treasurer, presided. The secretary, Mr. George J. Ingram, read the report of the Committee and balance-sheet for 1918. They were as follow :—

REPORT OF THE COMMITTEE.

In presenting their 79th annual report, with statement of receipts and expenditure (as audited), the committee desire to express their deep thankfulness at the cessation of the war, which for the past 4½ years has caused so much sorrow and distress in every part of our land, and they hopefully now look forward to an era of peace and brighter times, when our old-established charities will again—now that the demands on the benevolent public so necessary in connection with the recent terrible struggle, may be expected to diminish—enjoy a more generous support in carrying on their work.

The Gardeners' Royal Benevolent Institution has been established as a National Horticultural Charity for 79 years, and during that time has afforded assistance with inestimable benefit to a large number of poor old people who found themselves, through no fault of their own, in such circumstances of need as to oblige them to seek its aid.

At the commencement of the year there were 262 annuitants on the funds—men and widows. During the year several men have passed away (four of them), leaving widows, who have been placed on the funds without election, in accordance with the usual rules in such cases. To-day, fifteen candidates are recommended for election from an approved list of fifty-eight applicants. The committee had hoped to propose a larger number for permanent assistance, but they feel that with the diminished income of the past four years, due mainly to the absence of the usual Festival Dinner, hitherto the chief source for raising funds, it would not be prudent at the present time to add to their liabilities, much as they would like to do so; although, unfortunately, more than forty candidates will perforce be left over at the election, it is a comfort to know that substantial assistance is afforded them while on the waiting list from the "Victorian Era Fund," as well as temporary help from the "Good Samaritan Fund," is given to other distressed applicants. It may be well to remind subscribers and others that the interest only is available from these two funds, so that special contributions in augmentation of either of them will be warmly welcomed.

The committee have again to acknowledge the gracious kindness of Her Majesty Queen Alexandra in personally allocating a grant of money from the proceeds of "Alexandra Day." They are also deeply grateful to an anonymous, very warm-hearted friend of the institution for his generous offer of £250, on condition that £750 be obtained, or £500 if the sum of £1,500 were secured, and although the larger amount was not realised, the donor has most liberally given £500, and promised the same amount during the present year. Sincere acknowledgment is also accorded to Heber Mardon, Esq., for his [illegible] gift of £100 National War Bond.

The Committee have pleasure in recording their very sincere and grateful thanks for the helpful kindness of those noblemen, ladies and gentlemen who have again permitted their gardens to be opened to the public for the benefit of the Charity, viz. :—

The Rt. Hon. Earl Beauchamp, Rt. Hon. Lord Northbourne, The Lady Battersea, Sir Frank Crisp, Bart., Dyson Perrins, Esq., and Roger J. Corbet, Esq.

They also gladly refer to the kindness of the treasurer (Sir Harry J. Veitch), Arthur W. Sutton, Esq., and Geo. Monro, Esq., in giving a year's allowance to three of the unsuccessful candidates, one man and two widows, who are very grateful for the timely aid thus afforded them.

Very sincere thanks are tendered to the honorary auditors, Messrs. George H. Cobley and Co., for their kind services; also to the honorary solicitors, Messrs. H. Morgan, Veitch and Bilney; to the horticultural Press and other friends for their invaluable help.

Grateful thanks are likewise given to the following honorary officers of the several Auxiliaries who have done so much in furthering the interests of the Institution :—

LIVERPOOL.		
The Rt. Hon. the Earl of Derby, K G.	A. J. Cripping, Esq	Mr. R. G. Waterman

In this connection the Committee would specially mention the sad loss the Institution and the Worcester Auxiliary have sustained by the death of their friend Mr. Harry J. White, who for the past four years had acted as honorary secretary. Full of enthusiasm and energy for the cause, the Institution owed him a great deal, and he will be much missed.

It is with much sorrow and regret the Committee have also to record the deaths of many other warm friends and supporters during the past year, foremost amongst whom were Alfred de Rothschild, Esq., C.V.O., a vice-president who, with his family, had generously supported the Institution for 60 years; the Lord Brassey, Sir Geo. Malcolm Fox, Robert Gordon, Esq., E. Goodyear, Esq., and William E. Green, Esq.

In conclusion the Committee very earnestly appeal—in this first year, as all hope, of a permanent peace—for a generous and liberal support to enable them to continue the praiseworthy work of providing assistance for those distressed horticulturists in their time of need and urgency who seek its help. *Harry J. Veitch, Chairman and Treasurer; George J. Ingram, Secretary.*

The chairman moved the adoption of the Report and Balance-sheet. He was glad that the Institution had been able to continue its good work during the past four years, but regretted that the Committee had not the means to relieve all the necessitous cases that came before it. At the present time there were 43 applicants seeking benefit, but even next year it would be impossible to put all the forty-three on the Funds. He was glad, however, that some measure of relief could be afforded them from the Good Samaritan and Victoria Era Funds. During 1918 the sum of £450 had been allotted from these two funds in addition to what had been disbursed in pensions. The Institution had had to meet increased expenses during the past twelve months: to mention only one item, the cost of the voting papers was now three times what it was before the war.

Their secretary had, however, done his utmost to economise, and for a long time he had been working single-handed. Sir Harry Veitch reminded his hearers that a considerable amount of the Institution's revenue had been obtained in the past through the annual festival dinners, but these had to be abandoned in war-time. Now that peace was again in sight he appealed to the supporters of the Fund to help to make up some of this loss.

Continuing, he said it would be remembered that last year an offer was made by an anonymous friend of a gift of £250 provided three other donors gave the sum of £250 each, and £500 of the sum of £2,000 was obtained. He was now at liberty to announce that the offer was made by Mr. Reginald Cory, who generously gave the larger sum, although they had not been successful in raising the amount stipulated. Mr. Cory had promised them a similar amount in 1919. With regard to the festival dinners, as soon as the armistice was declared the Committee decided to hold a dinner as usual in 1919, and the Worshipful Company of Grocers had generously placed their Hall at the disposal of the Committee for the purpose. The date had been fixed for June 19, and he, Sir Harry Veitch, had consented to occupy the chair. He appealed for support on that occasion, and asked all horticulturists to "back him up." The various auxiliaries had done well, and he specially mentioned Reading and Worcester, the latter town having recently sent the secretary nearly £100. From Sir Frank Crisp the sum of £50 had been received, being part of the proceeds received from a small fee paid by visitors inspecting the gardens at Friar Park. The Fund had received a special gift of £150 for deserving cases, and it was proposed to divide the money between the unsuccessful candidates.

Mr. Arthur Sutton seconded the adoption of the Report. Referring to the small number present, he suggested that it showed the confidence of the subscribers in the Committee. He urged that a special effort be made to augment the emergency fund, which was almost exhausted. The meeting then proceeded to the election of officers. Sir Harry Veitch was re-elected chairman and treasurer, and Mr. Geo Ingram secretary. The retiring members of the Committee, the auditors and arbitrators, were all re-appointed. At this stage of the proceedings the meeting was adjourned for the counting of the ballot, and later the successful candidates were announced as follow:—

Result of Election.

	Age.	No. of Votes
Pugh, Mary	80	4,656
Brodie, Malcolm	73	4,250
Bryden, Robert	64	4,085
Wilkins, James	72	3,985
Sparks, Louisa J.	64	3,843
Faint, Francis	68	3,779
Taylor, William	74	3,649
Wilson, Jane A.	76	3,620
Earl, Elizabeth E.	72	3,596
Bridges, Charles	75	3,585
Hampton, Harriet	83	3,532
Marlow, William D.	76	3,528
Meadows, Mary E.	67	3,329
Astridge, Mary A.	62	3,310
Farrant, William	72	3,044

Mrs. Eliza Dillistone was placed on the funds without further voting, by resolution, under Rule III., 10.

Mr. Arthur W. Sutton announced his desire to give the sum of £20, equal to one year's allowance for an unsuccessful male candidate, and Sir Harry J. Veitch offered £16, for one year's allowance to a female candidate. Mr. George Monro also gave a donation of £10, to be given to one of the unsuccessful candidates who is a widow.

BRITISH FLORISTS' FEDERATION.

January 23.—The interest and enthusiasm shown by those present at the annual general meeting of the B.F.F., at Essex Hall, Strand, W.C., were evidence of the excellent relations existing between the management and the general body of members.

Mr. Geo. Monro, junr., presided, and members were present from the suburbs of London and from Sheffield, Bedford, Dover, and other parts of the provinces.

On the motion of Mr. A. M. Wilson, seconded by Mr. Milton Hutchings, the report and accounts were adopted. We give the following extracts therefrom:—

At the end of 1917 a membership of 172 was recorded. There are now 277 members, and thanks are due to those gentlemen who have worked hard and effectively to secure new members, especially to Mr. Robert H. Page and Mr. Brayshaw, who were particularly successful in this direction. A balance of £9 12s. 4d. was brought forward from 1917, and one of £17 1s. 3d. is now carried forward. The Federation is in no sense a London concern, as it has members in Scotland, Ireland, Wales, Guernsey and Jersey, the Scillies and most of the English Counties.

Members of the Federation patriotically carried out the voluntary agreement to reduce flower growing and increase food production by at least 50 per cent., as a war measure. In response to a request by the Food Production Department all members were asked to fill up and return a prepared schedule. From 150 returns received the following totals have been compiled:—

	Acres	roods	rods
Area of Holdings	6,858	1	20
Area of Arable Land	4,881	0	6
Area of Grass Land	1,460	0	10
Land under Flowers in 1914	1,775	1	34
Land under Flowers in June, 1918	699	3	23
Area of Glass-houses	319	0	35
Area of Glass under Flowers in 1914	218	1	24
Area of Glass under Flowers in June, 1918	76	0	23
Area of Glass devoted to Food Production in June, 1918	222	0	9
Area of Land devoted to Food and Seed Production in June, 1918	4,143	1	39

During the year the offices of the Federation have been used by several trade and horicultural societies as their position in Covent Garden makes the rooms most convenient for committee meetings. The Horticultural Trades' Association has held its monthly council meetings there, and the London Retail Seedsmen's Association, the National Chrysanthemum Society, the National Sweet Pea Society, the National Dahlia Society, and the British Carnation Society have also found suitable accommodation, consequently the home of the British Florists' Federation has become a centre of horticultural activity. Further, the Horticultural Club's pictures and books are being housed at 35, Wellington Street, Covent Garden, until the Club has a home of its own again.

It is a matter of special interest that the control of Raffia has been removed as a result of the representations made by the Committee to the Board of Agriculture and the Food Production Department directly after the armistice was signed on November 11. Notwithstanding the lateness of the season for securing importations of Lily bulbs from Japan, the Committee approached the Board of Trade Department of Import Restriction directly after the conclusion of hostilities, and asked that opportunity to import bulbs, chiefly of Lilium longiflorum and Lilium speciosum, should be granted. Aware of the work flower growers had accomplished in the production of food, Dr. Keeble urged that a concession should be made. Eventually a concession was made, and the De-

partment agreed to allow the importation of 10,000 cases of bulbs. It is doubtful whether importations can be obtained as the season was far advanced, available shipping space small and freightage charges high, but the Committee did the best it could for the trade by acting with the utmost promptitude.

The compilation of the Credit Index has proceeded steadily through the year, and has now reached a point where it will be really useful.

Hitherto, unless members have been in direct communication with the Secretary, their knowledge of the business proceedings has been limited to the generous references made in the Horticultural Press to special matters which have arisen. The publication of a Bulletin has been under consideration for some time, and was approved at a meeting in September. The Bulletin will appear at intervals, as the Committee may determine, and will be sent to every member.

In the early part of the year 1918 a movement was started with a view to securing the co-ordination of the various horticultural societies and federations, and creating an effective central authority. This movement—in which the President and Secretary have taken an active part—resulted in the inauguration of the Chamber of Horticulture, with the approval and good wishes of the Rt. Hon. R. E. Prothero, President of the Board of Trade; Dr. Keeble, Controller of Horticulture, and many other influential people. The Committee considers such a central body should be heartily supported, and recommends the attachment of the Federation thereto.

The officers and committee were heartily thanked for their services. Mr. Geo. Monro, junr., was re-elected president, and Messrs. G. H. Cobley and Co. hon. auditors. As a result of the ballot Messrs. W. A. Cull, F. W. Ladds, A. Mizen, S. M. Segar, E. Stevens, E. T. Wheaton and A. M. Wilson were re elected members of the committee, and Messrs. W. G. Innes, . Lambert and H. J. Gay were elected to fill vacancies arising from resignations.

After fully discussing the matter the meeting unanimously agreed "That the British Florists' Federation become attached to the Chamber of Horticulture." In reply to one question raised Mr. Monro stated that private members of the Chamber would in no sense have a controlling interest, as their representation was limited by rule.

The president invited suggestions and criticism at the close of the regular business, and the opportunity thus afforded was taken full advantage of. Mr. Monro stated that while flower-growers should not revert wholly to flower cultivation, they would be at liberty to gradually reduce their cultivation of foodstuffs. It was agreed that a protest against the importation of Dutch flowers should be made to the Board of Trade, and that the Prohibition Order should be enforced in this case. The proposal on the part of America to prohibit the importation of most European horticultural produce gave rise to considerable comment, and it was agreed that the Federation request the Chamber of Horticulture to approach the American Embassy, the Board of Trade, and the Belgian and French authorities, with a view to obtaining a reversal of this proposal, as a general prohibition of this kind would, if enforced, prove a great hardship to French and Belgian as well as British horticultural traders.

After the secretary, Mr. Chas. H. Curtis, had outlined the scope of the proposed bulletin, the proceedings concluded with a vote of thanks to Mr. Monro for presiding.

THE LATE GEORGE BUNYARD, V.M.H.

SCOTTISH HORTICULTURAL.

JANUARY 14.—The annual business meeting of this Association was held at Dowell's Rooms, 18, George Street, Edinburgh, on this date. Mr. Robert Fife, the president, was in the chair, and there was an attendance of about 80. The report by the Council stated that the ordinary work of the session had been carried on as usual, and that the average attendance at the monthly meetings was higher than in the two preceding sessions. Owing, however, to the war, and to a heavy death-roll, there was a marked decrease in the membership. No fewer than four of the twelve honorary members had passed away during the year, viz., Messrs. Alex. Mackenzie and Matthew Todd (two of the original members of the Association), Sir M. Mitchell Thomson, Bart., and Mr. Peter Loney, who for a number of years acted as honorary secretary. Over 130 members were serving with the Army and Navy, and 12 had made the supreme sacrifice. It was the intention of the Council, however, to take measures in the current session to have the membership put on a satisfactory footing.

It was intimated that the Association had decided to hold a Scottish National Potato Exhibition in the Waverley Market, Edinburgh, on October 29 and 30, and that the preliminary prize list of the Exhibition was almost completed, and would be issued immediately. It was also intimated that the venture had received financial and other support from the Corporation of Edinburgh, the Highland and Agricultural Society of Scotland, the Board of Agriculture for Scotland, and a considerable number of gentlemen interested in the promotion of the Exhibition, that the guarantee fund amounted to £1,000, and donations to the Prize Fund amounting to over £300 had been announced. A number of special prizes for fruit and vegetables had also been offered.

The Most Hon. the Marquis of Linlithgow was re-elected honorary president, and Mr. Fife was re-elected president for 1919. Messrs. D. King and J. Dobbie were elected vice-presidents in place of Dr. Smith and Mr. H. Thomson, who retired by rotation, and the secretary and treasurer, Mr. A. D. Richardson, and the auditors, Messrs. Robertson and Carphin, C.A., were re-elected. Of 14 candidates for eight vacancies in the Council the following were elected: Messrs. J. Highgate, Hopetoun Gardens, West Lothian; Malcolm Phillips, Granton Road Nurseries, Edinburgh; R. L. Scarlett, C.D.A., Sweethope, Midlothian; Jas. Fraser, Bonaly Gardens, Midlothian; J. Rowe, Princes Street Gardens, Edinburgh; J. L. Forbes, Edinburgh; A. M. Crabbe, Edinburgh; R. T. Naismith, Edinburgh.

Owing to the falling off in subscribers, due to the war and other causes, there was a deficit of approximately £80 on the revenue account for the year.

Obituary.

George Bunyard.—The death of Mr. George Bunyard, V.M.H., on January 22, as reported in *Gard. Chron.*, January 25, p. 48, removes a notable personality from the world of horticulture. Tall, and gifted with a fine presence, endowed with great ability as an organiser, possessing a wonderfully wide knowledge of fruits and of the nursery and fruit trades, he also had a kindly and gracious manner, which enabled him to make, and keep, a very large number of friends, consequently the loss created by his death will be deeply felt far outside the family circle. Born in 1841, Mr. George Bunyard entered his father's office in 1855. Commencing in the seed department, he subsequently acquired a thorough knowledge of fruits, conifers, hardy shrubs, and herbaceous plants. At that early period the firm did only a local trade, but from time to time more land was taken, and a great advance was made in 1869, when the now famous Allington Nurseries were started with 20 acres. The utmost secrecy was necessary in obtaining the land, as farming was a good business then, and it was only by careful diplomacy that new acreage could be secured. The nurseries now extend to 166 acres. In 1863 Mr. George Bunyard was made a partner, and the business was extended in all directions. He was a prominent member of the great Apple Conference, 1883 where his expert knowledge proved of such great value that he was made chairman of the Fruit Conference held at Edinburgh in 1886. He was the moving spirit in carrying out the City Exhibition of Fruit, held at the Guildhall, London, in 1890, for which service the Fruiterers' Company made him a freeman of the City. In 1896 he became Master of the Company, and celebrated the occasion by entertaining the Lord Mayor and Sheriffs and a large gathering of gentlemen at De Keyser's Hotel. He was one of the first to receive the Victoria Medal of Horticulture, and served for 34 years

on the Fruit Committee of the Royal Horticultural Society, and for about ten years was a member of the R.H.S. Council. When his health failed, the Fruit Committee gave him a handsome present and a framed address of appreciation; but the Committee had previously—on the occasion of its Jubilee in 1909—presented him with his portrait, which now hangs in the Committee Room at Vincent Square. Mr. Bunyard's chief interest was in connection with fruit, and his firm were champion exhibitors for 25 years. By means of lectures, *Fruit Farming for Profit*, *The Fruit Garden*, articles in the *Century Book of Gardening*, and contributions to the *Gardeners' Chronicle*, he stimulated the market culture of fruit on the Kent system. Among new fruits, his notable introductions were Superlative Raspberry, Allington Pippin, Lady Sudeley, Market Favourite, Gascoyne's Scarlet, and Hambling Seedling Apples, while many little-known fruits were brought to notice by his firm. He spared no pains to produce the best possible fruit trees in all forms, but at the same time large collections of Roses, Rhododendrons, and other flowering shrubs, trees, and plants were made and maintained. He made his business a large and prosperous one, and since his retirement from the active management he wrote: "The business has prospered still more under the guidance of my two sons, Edward Ashdown and George Norman, since illness and old age have compelled their father to give up active work." The funeral took place at Mereworth on the 22nd ult., amid every expression of respect. The Rev. W. Wilks was unable to attend, but the Royal Horticultural Society sent a wreath of Laurel with the inscription, "A very small recognition of many long years of assistance and advice given so willingly to the Royal Horticultural Society by Mr. George Bunyard, V.M.H., from the President, Council, Secretary, Fruit Committee and Staff of the Society.

John Black.—We regret to record the death at Preston Mains Farmhouse, East Lothian, of Mr. John Black, for many years gardener to Sir A. Buchan-Hepburn, Bart., at Smeaton, Prestonkirk, East Lothian. Mr. Black was one of the ablest and most esteemed of Scottish gardeners, and the gardens at Prestonkirk, full of subjects of great interest, were ably managed by him. He retired a short time ago.

CROPS AND STOCK ON THE HOME FARM.

SHEEP.

If I were asked to name the most popular breed of sheep for general utility use I should say at once Hampshire Downs. On an arable farm where close folding is essential for the welfare of the corn crops and for hardiness and quick growth of the lambs, this breed is highly prized, not only in Hampshire, but in many other counties. For crossing with other breeds, especially Southdowns, this breed is popular. The bulk of flocks this season are later in lambing than usual as a result of the suggestion that lambing should be deferred owing to the probable scarcity of feeding stuffs, a suggestion farmers readily adopted for the common good. In normal times lambing commences the first week in January, and by the middle of May lambs weighing 60 lbs. are obtainable. This season we are a month later, and there may be some benefit derivable from the change, such as better weather and a saving of food, material and losses. In preparation for the lambing season great care in feeding the ewes must be exercised; in no circumstances should they be given frozen food, or abortion will follow and much loss be experienced. Hay of good quality is essential to success at this stage, and one of the safest of foods to give in the morning and again in the evening. Gentle exercise is important, but there must be no excitement.

A fortnight before lambing time each ewe should have a half-pound each of Cotton and Linseed cake per day. If the ewes have had a small quantity of Turnips during the past two months no harm will result from the continuation of this food, but otherwise do not give Turnips nor any other roots until after lambing has taken place, when two Turnips per day, in addition to the hay, may be allowed. Water is necessary when hay is used, therefore clean water should always be available. Warm cow's milk should be given to lambs that need it, and it is often a means of saving the lambs from death.

A properly made lambing pen should be dry and fairly warm, and sheltered from north and east winds as much as possible. A square yard should be provided, with small pens around the outside so arranged that they provide the shelter for the yard; each pen should be about 4 feet square, which allows ample space for one ewe and two lambs, and the necessary food and water. The ewe should remain in the pen for four or six days if all goes well, when she may be moved into a more open part of the yard, where the lambs will obtain more exercise and air, while the ewe has an increase of food as the lambs progress. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

TRADE NOTES.

SEED GERMINATION.

The Board of Agriculture, the Board of Agriculture for Scotland, and the Department of Agriculture and Technical Instruction for Ireland, have authorised the sale for seed of Tares or Vetches, field Turnip, Swede, Rape, field Cabbage, field Kale, field Kohl Rabi, and Mangel without declaring the actual percentage of germination. This percentage, however, must be not less than the following standard of germination, and a statement to that effect must be made: Tares or Vetches, 90; field Turnip, 85; Swede, 85; Rape, 85; field Cabbage, 75; field Kale, 75; field Kohl Rabi, 75; and Mangel, 120 per cent.

Hyacinths, Roman, 12's, per doz. bun.	3 6- 4 0	Violets, single, per doz. bun.	6 0 10 0

REMARKS. White flowers, such as are required by florists, are chiefly confined to Azalea and White Narcissus. Chrysanthemums are practically over for the season. A few boxes of Allman's Yellow are still offered in good condition, but these are the last of the coloured varieties that can be termed sound and saleable. Paper-white Narcissus being more in demand, and supplies somewhat limited: prices are firmer. Larger quantities of Mimosa are being received. Amongst the French flowers the most attractive lines are Anemones, Ranunculus, and Parma Violets. Anemone De Caen, single mixed, are selling freely. The chief fresh arrivals during the past week have been Pheasant-Eye Narcissus and Tulips—White La Reine, Prince of Austria, and mauve William Copeland. The new season's Roses have begun to arrive, and a few blooms of Richmond sold freely last week. A few bunches of Forget-Me-Nots are on sale.

Trade is very quiet in the pot-plant department, and weather conditions are against plentiful supplies just now. A few pots of Daffodils and Pheasant-Eye Narcissus were offered for sale during the week. All Ferns are scarce, and the quality cannot be termed first class; but an improvement cannot be expected for a few weeks yet.

REMARKS.—Supplies of black Grapes may be said at present to be sufficient for the demand, and the market is well supplied with Almerias. Californian E. B. Pears are on offer. The following forced vegetables are now available:—Dwarf Beans, Mushrooms, Seakale, Chicory, Asparagus, Cucumbers, New Potatos, and Mint. Ordinary vegetables are plentiful, the market being well supplied with all seasonable kinds.—*E. H. R., Covent Garden Market, January 29, 1919.*

ANSWERS TO CORRESPONDENTS.

CALCIUM SULPHIDE AND WIREWORMS: *H. N.* Probably the horticultural sundriesmen who advertise in our columns will be able to supply you with calcium sulphide. The other points raised in your letter will be referred to in an early issue.

EMPLOYMENT IN AN ESTATE OFFICE: *J. K.* The prospects of employment in an estate office are fairly good, and a young man who has a knowledge of gardening, farming and timber should find congenial employment in the work. To be successful a knowledge of surveying, accounts, sales and costing is necessary. Apply for particulars to a firm of estate agents.

PROFITABLE MARKET GARDENING: *H. W.* Given soil of fair quality and a suitable site, market gardening is a profitable business in the hands of a man who possesses knowledge of the work and skill in its practical application. Success depends largely upon the rapidity with which one crop is cleared and followed by another, and a good market that can be easily reached. The gross cash return per year per acre varies immensely, and where one grower would fail another would do well, therefore any figures we might give would be misleading, especially as you have given no particulars as to the kinds of crops you propose to grow. You could work out approximate figures by estimating the number of Cabbages per acre (allowing for losses in the rows) and pricing them at the average market value per tally in the season in which they would be ready; the acreage per acre, for the district, would give a basis of returns for the Potato crop, and other crops could be estimated on similar lines. The Board of Agriculture may be able to help you in this connection, but practical experience is worth more than many figures.

SEWAGE SLUDGE AND FLUE DUST: *J. H.* The composition of sewage sludge varies very considerably according to the method by which it is treated, and particularly its composition depends on whether lime is used in precipitation. The following is a fairly average analysis of sludge: Moisture, 48.7; organic matter, 19.0; mineral matter, 31.0; total nitrogen, 0.86; ammoniacal nitrogen, 0.06; phosphates, 1.11; potash, 0.29; and lime, 13.27 per cent. It would probably be advisable for you to get analyses made of both the flue dust and the sludge, and you can probably arrange for this to be done through the Chemical Department of the University of Wales at Cardiff. Full information with respect to flue dust is contained in Food Production Pamphlet No. 23.

ORCHIDS.—Calanthe Harrissi, white; Calanthe Veitchii, deep pink variety; clean, fine specimen bulbs.—Particulars, WEST, Nurseries, Datchet, Bucks.

FERNS! FERNS!!—Tree Ferns, Climbing Ferns, Basket Ferns, Stove and Greenhouse Ferns, Hardy Garden Ferns; catalogues free. — J. E. SMITH, London Fern Nursery, Loughborough Junction, London, S.W 9.

PERPETUAL FLOWERING (American) CARNATIONS.—Price list now ready. My stock is in perfect condition. Inspection invited.—C. ENGELMANN, Saffron Walden, Essex.

CALANTHE Veitchi for sale, strong, healthy bulbs, 25s. per doz., carriage forward.—Apply, J. CARTLEDGE, The Gardens, Butterley Hall, Derby.

CHRYSANTHEMUM CUTTINGS, market varieties; trade prices. List free.—CLEVEDON ESTATE NURSERIES, Clevedon, Somerset.

LIMITED quantity of Box Edging for sale. — FRED E. SPITTLES, 121, Semilong Road, Northampton.

SEABROOK'S BLACK CURRANT CUTTINGS for sale; best big bud resisters, 10s. 6d. per 100, 80s. 1,000, carriage paid.—RIGGALL, Newbury.

RHUBARB. – Champagne, clumps for forcing, 10s. per doz., 80s. 100; planting sets, 3s. dozen, 25s. 100; Dawes' Champion, 35s. 100 sets; on rail, for cash only.—J. HANDSCOMBE, F.R.H.S., Feltham Nurseries, Middlesex.

ASPARAGUS for forcing.—Extra fine transplanted roots, 21s. to 30s. per 100. Sample sent for 12 stamps.—WILL TAYLER, Hampton, Middlesex.

BIRCH BROOMS, 8s. dozen; quantities cheaper. Cash with order, on rail. HENRY SELL, Elmbrook Road, Cheam, Surrey.

PEARS.—Well-spurred, Fruited Cordons, 5 to 7 feet; Doyenne du Comice and other leading varieties.—WILL TAYLER, Hampton, Middlesex.

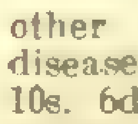
FRUIT TREES. — 12 Nectarines, 5 Peaches, in pots, well set with fruit buds. What offers?—AKERS, Codicote Lodge Gardens, Welwyn.

100,000 LARGE GARDEN FERNS, 24s. 100; Palms, Begonias, Crotons, Dracaenas, Roses, Ericas, Gloxinias, Lilies, Hydrangeas, &c.; catalogues free.—J. E. SMITH, London Fern Nurseries, Loughborough Junction, London, S.W. 9.

MISCELLANEOUS.

OILSKINS THAT DO NOT STICK.

Oilskins that will give you good service and stand hard wear. Oilskins that never fail to keep out the hardest rain or sleet—BEACON OILSKINS. Men's Coats from 25s., Long Leggings from 5s., Sou'-westers 3s., Children's Coats 16s. 6d. upwards. Ladies' Smart Oilskins, 28s. 6d. Deal direct with us and save money. Send a postcard to-day for our Free Booklet of "Weather Comfort," describing money-back guarantee. —Send now—before you forget—to BARBOUR'S, LTD., 66, BEACON BUILDINGS, SOUTH SHIELDS. (3)



"PESTITE" kills wireworms, rook-worms, cockchafer grubs, Julus worms, and other soil pests; also "club root" and other fungoid diseases. Price: 28lbs. 5s. 6d., 56lbs., 7s. 6d., 112lbs. 10s. 6d., 1 ton £8, all carriage paid, from G. LANG & SONS, LTD., Hounslow, Middlesex.

BANSTEAD or WALTON HEATH LOAM.—A splendid soil for all purposes; fresh cut or rotted.—Particulars of YOUNG BROS., Betchworth Surrey.

A TIME SAVING BOON An Unique Green Clouding, mixed and removed with simply Cold Water. Lasts whole season Elliott's New Summer Shading "PINGO" for Greenhouses. R.H.S. Medal awarded TRY IT Pkts 1/6 or 7-lb bags 15/6, of Seedsmen, or carr paid, of Maker F. ELLIOTT, ALFRED ROAD, LONDON, W. 3.

SEED POTATOS. — Epicures, 10s. cwt.; Sharp's Express, 14s.; Maincrops, 8s. 6d. Send for price list.—W. J. PLAYER, High Ridge Farms, Haddenham, Cambs.

CONSERVATORY for sale, 36 by 14 plate glass front, with boiler and pipes, complete, in first-class condition.—Apply, G. POCOCK & SON, Temple, Fortune Lane, Golders Green.

FOR SALE, new corrugated Iron Sheets, at following prices:—6ft. 6s., 7ft. 7s., 8ft. 8s. 2d., 9ft. 9s. 3d., 10ft. 10s. 6d.; carriage paid; immediate deliveries; all painted ready for fixing.—Apply, BUILDER, 48, Well Street, Hackney, London.

STRONG stakes for Rose Trees and similar purposes; 1 to 1½ inches diameter; at ½d. per foot length any length up to 8 feet.—COLEMAN & SONS, Cranfield, Beds.

WANTED, Motor Lawn Mower, 24in. or 30in. size.—Price, make, &c., to G. W. YOUNG, Rampton Manor, Retford.

SITUATIONS VACANT.

Twenty words (or three lines including headline) 3s. and 6d. for every succeeding eight words (or line) or portion thereof. Fee for having replies addressed to this office. 6d.

Gardeners desiring their Advertisements repeated *must give full particulars, otherwise no notice will be taken of their communications. Name and address alone are insufficient.*

Gardeners writing to Advertisers of Vacant Situations are recommended to send them **copies** *of testimonials only, retaining the originals. On no account should they enter into communication with unknown correspondents who require a fee beforehand.*

Advertisers are cautioned against having Letters addressed to Initials at Post-offices, as all Letters so addressed are opened by the Postal Authorities and returned to the Sender.

PRIVATE.

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE.
THE GOVERNORS invite applications for the post of CHIEF LECTURER IN HORTICULTURE. The commencing salary is £250 per annum, and the person appointed must devote his whole time to the work. Applications, accompanied by 25 copies of three recent testimonials and by a statement of age, present employment, professional training, practical knowledge, and lecturing experience (if any), must be lodged with the undersigned not later than 17th FEBRUARY, 1919.
JOHN CUTHBERTSON, Secretary.
6, Blythswood Square, Glasgow.
3rd February, 1919.

COUNTY COUNCIL OF DURHAM.
HORTICULTURAL ADVISER and LECTURER required. Initial salary £200, with travelling expenses. Particulars of duties, &c., may be obtained from the undersigned, to whom applications must be sent in before SATURDAY, 15th FEBRUARY, 1919.
J. A. L. ROBSON,
County Secretary for Higher Education.
Shire Hall, Durham.
3rd February, 1919.

WILTS COUNTY COUNCIL.
AGRICULTURAL EDUCATION COMMITTEE.
EXPERT IN ORCHARD MANAGEMENT.
REQUIRED, for itinerant work throughout the county, an EXPERT in Orchard Management, who would also act as an INSTRUCTOR in Fruit Culture. Applications, stating experience, and salary desired, to be made to
C. H. CORBETT,
Secretary and Organiser.
Agricultural Education Department,
County Offices, Trowbridge.

BRITISH GARDENERS' ASSOCIATION.
(Reg. No. 1666 T.)
THE B.G.A. has adopted a new standard of wages and hours, and employers and employees may obtain a copy by sending stamped foolscap envelope to the General Secretary. Before accepting fresh situations, demobilised men are advised to write the General Secretary, B.G.A., 22, Buckingham Street, Strand, W.C. 2. Journeymen are required for good situations. Send full particulars of past experience.

GARDENER (HEAD WORKING) required to cultivate and manage Garden and grounds, Vinery and two small Greenhouses, of Wilburton Manor House, 6 miles from Ely; situated close to village; railway station ¾ mile; Under Gardener employed. State age, family, and wages required; good references.—Apply to MESSRS. BIDWELL & SONS, Land Agents, Ely, Cambs.

WANTED, GARDENER (SINGLE-HANDED); thoroughly capable, Inside and Out, and trustworthy to leave in charge in owner's absence; a little Glass (Vine, Tomatos, and Cucumbers), Kitchen Garden, Fruit, Flower Borders, &c.; skilful Gardener essential; cottage rent free on the spot.—Wages required and references to EVANS, Nurseries, Llanishen, Cardiff.

GARDENER wanted; good single-handed; married (no children); wages 35s.; small lodge and vegetables.—CAMPBELL-JOHNSTON, Westwood, Ascot.

SINGLE-HANDED GARDENER wanted; chiefly for Vegetables and Fruit; wages 36s.; no cottage.—Apply by letter, K., Woodside, Stanmore, Middlesex.

SINGLE-HANDED GARDENER required for Flower and Vegetable Garden. Applicant kindly state wages and particulars of experience. — LT.-COLONEL HARRISON, Harthover, Blackwater, Hants.

GARDENER wanted; married man; thoroughly experienced in Herbaceous and Hardy Plants, Lawns, &c.; wages 32s. to 35s.; cottage and garden found.—Apply, with references and experience, to HEAD GARDENER, Wittington, Marlow.

GARDENERS required; one married and two single MEN for Pleasure Grounds and Kitchen Gardens.—Experience and wages, JONES, Shirenewton Hall, Chepstow.

WANTED, GARDENER, single; splendid home; live in; all found; good pay; must understand Flowers and Vegetables.—67, Wigmore Street, W.

WANTED, GARDENER; must be able to use a scythe; help given with digging, &c.; principally outdoor work; cottage found. State all particulars. Good wages given.—G. H. RICHARDS, Arne House, Woldingham, Surrey.

WANTED, a MAN, for Rock Garden and Herbaceous Borders; a good knowledge of Hardy Plants essential; substantial wages given; 1 o'clock Saturdays.—State age and experience to T. W. BRISCOE, The Gardens, Castleford, Chepstow.

WANTED, LEADING HAND, for Pleasure Grounds; good knowledge of Rockery, Herbaceous, and Roses.—Send full particulars, copy of testimonials, wages expected, with Bothy and vegetables (1 o'clock Saturdays), to J. HOAD, Colworth Gardens, Sharnbrook, Beds.

WANTED, reliable MAN, single, to assist Head Gardener; good worker; must thoroughly understand Kitchen Garden work, Lawns, and Herbaceous Borders. Wages 30s.—Write, giving full particulars, age, experience, and references, to REV. H. MALLINSON, Woodlands, Ledbury, Herefordshire.

WANTED, thoroughly experienced MAN for Rock Garden and Herbaceous Borders. State wages, good Bothy and vegetables; 1 o'clock Saturdays; duty and overtime paid.—T. SIMPSON, The Gardens, Newstead Abbey, Notts.

WANTED, good MAN, for General Outside work; single; state age and experience; wages 32s. per week; no Bothy or stoking.—G. BROWN, Aston Hall Gardens, Derby.

WANTED, capable single MAN for Fruit and Plant Houses; also General Gardening; five kept; wages 35s to 40s.—Apply, giving full particulars, copies of testimonials, SEDEN, The Rookery, St. Mary Cray, Kent.

WANTED, good SECOND, for Fruit, Plant, and Orchid Houses; 36s.; no Bothy. Also good MAN, for Fruit Trees, Roses, Lawns, &c.; and a KITCHEN GARDEN MAN, who can take charge of two cows; each 34s.; no Bothy.—Apply, GARDENER, Feltham Lodge, Feltham, Middlesex.

WANTED, SECOND GARDENER, where three are kept; general experience and good references necessary.—Apply, Mr. W. McCALL, Woodlands, Walthamstow.

WANTED, UNDER GARDENER, experienced in growing Orchids; good opportunity for Improver; Bothy or cottage supplied, with free coal. State experience and wages wanted.—Apply, A. B., Box 19, 41, Wellington Street, Covent Garden, W.C. 2.

FOREMAN; thoroughly experienced, for Fruit and Plant Houses; must be specially good on Carnations, Cinerarias, and Chrysanthemums. State wages; good Bothy and vegetables; 1 o'clock Saturdays; overtime paid.—T. SIMPSON, The Gardens, Newstead Abbey, Notts.

WANTED, FOREMAN, for Fruit and Plant Houses. Also two IMPROVERS, one for Inside, the other for Inside and Out.—Apply, stating experience and wages expected, with Bothy and vegetables (12 o'clock Saturdays), to ATTLEASEY, Huntroyde Gardens, Padiham, Lancs.

WANTED, FOREMEN, for England and Scotland; Inside Journeymen and Outside Journeymen for first-class places.—State wages expected and all particulars to STEWART & CO., 13, South St. Andrew Street, Edinburgh.

FOREMAN wanted for Vegetable Department; well up in his work; good wages to suitable man. — Apply, MARTIN, Horticultural College, Swanley.

FRUIT GROWER (FOREMAN) wanted.—An experienced man, both in and outdoor.—Apply, HOLLINGTON, Forty Hill, Enfield.

WANTED, JOURNEYMAN, with some Inside experience; also single MAN as GROOM for two Garden horses; good wages and Bothy.—Apply, E. HILL, Osberton Gardens, Worksop.

WANTED, JOURNEYMAN, for Fruit and Plant Houses; must have had good practical experience; good wages, Bothy, milk, vegetables, and attendance.—Apply, with references, to F. SOMERFORD, Park Place Gardens, Henley-on-Thames.

WANTED, JOURNEYMAN (Inside); experienced in Fruit and Plant Culture; wages 30s., Bothy and attendance; 1 o'clock Saturday; 3s. for duty. State particulars.—JAMES S. KELLY, Claremont Gardens, Esher, Surrey.

WANTED, a JOURNEYMAN, for Fruit and Plant Houses. State age, experience, and wages required, with Bothy, vegetables, and attendance.—W. L. BASTIN, Buscot Gardens, Faringdon, Berks.

WANTED, JOURNEYMEN, for Fruit, Carnation, and Plant Departments.—State wages expected and all particulars to E. MATTHEWS, The Gardens, Moulton Paddocks, Newmarket.

WANTED, Two JOURNEYMEN; Inside, First and Second, experienced in Fruit and Plant Growing; discharged men preferred; state particulars of experience and wages required; Bothy and attendance provided to GEO. GURNEY, Bodnant Gardens, Taly-Cafn.

WANTED, Two JOURNEYMEN GARDENERS; Inside and Out; rooms provided.—Address, stating age, wages, previous experiences, HEAD GARDENER, Ridgehurst, Shenley, Herts.

WANTED, two JOURNEYMEN; one Outside, one Inside; Bothy, &c.—Wages and experience to H. WENMAN, Temple Newsam Gardens, Leeds.

WANTED, experienced young MAN, single; Inside and Out; lodgings found near Gardens. State wages.—C. LUXFORD, Walmsgate Gardens, Louth, Lincs.

WANTED, young MAN, chiefly Outside; Bothy, milk, and vegetables. State age, experience, and wages.—J. BENSTEAD, St. Nicholas Gardens, Richmond, Yorkshire.

WANTED, strong YOUTH, about 17; Inside and Out; duty alternate week; 22s. per week and rooms.—Apply, J. HIGGS, The Gardens, Biddulph Grange, Congleton.

WANTED, at once, married COUPLE, without children; man for boots, knives, stoking, yard work, &c., in young ladies' school; wife for occasional work in the house; good wages, cottage, and coal.—Address, MISS WALLIS, Highfield, Oxhey Lane, Watford.

WANTED, GARDEN LABOURER, with wife to do laundry work and care of chickens; wages 30s., good cottage and garden; laundry work and chickens paid extra. — Apply to HEAD GARDENER, Ellisfield Manor, Basingstoke.

WANTED, a GARDEN LABOURER; good all-round man; able to use scythe; wages 36s. per week; cheap house and garden.—Apply, G. COOPER, Margam Park Gardens, Port Talbot.

TRADE.

REQUIRED, FIRST-RATE MANAGERESS or MANAGER for Food Production in Garden: must thoroughly understand the culture of Fruit, Early Vegetables, Tomatos, and Forced Vegetables under Glass; Violets and Carnations a speciality; also Mushrooms; good salary and share in profits.—MRS. GEOGHEGAN, Bert House, Alty, Co. Kildare, Ireland.

WANTED, experienced GROWER for Bedding Plants (market sale). Also a SECOND MAN, with some knowledge of Plants.—THOMAS PERKINS & SONS, LTD., 34, Drapery, Northampton.

WANTED, experienced GROWER, Cyclamen, Chrysanthemums, &c. Also a Horticultural Glazier. State experience and wages required. — G. CLARK, The Nurseries, Priory Lane, Putney.

ROSE GROWER, entire charge.—Advertiser, with heavy retail trade, offers position in a thousand to live man, capable of producing high-class stuff in quantity.—M. R., Box 16, 41, Wellington Street, Covent Garden, W.C. 2.

ROSE GROWER wanted; must be an energetic man; quick and successful budder.—Apply, stating experience, age, and wage required, to A. B., Box 17, 41, Wellington Street, Covent Garden, W.C. 2.

EMPLOYMENT offered to Two fully experienced CHARGE HANDS for Cucumber and Tomato Houses; wages £3 per week and extras.—Apply personally or by letter to WYNN HAMILTON, "The Ivies," Crossbrook Street, Waltham Cross.

NURSERY WORKERS. — Qualified Cucumber and Tomato Hands (male) wanted, in the neighbourhood of Waltham Cross; wages from 50s. per week, according to experience; extra for overtime and a bonus on production. GENERAL NURSERY HANDS also required; wages from 38s. per week; overtime extra. — Apply, Box 99, "Weekly Telegraph" Office, Waltham Abbey.

GLASSHOUSE MAN wanted (single preferred) for Market Nurseries; seaside town, West of England; wages offered 50s.—Send particulars of experience, &c., to O. H., Box 23, 41, Wellington Street, Covent Garden, W.C. 2.

FOREMAN (WORKING); Glass; North of England; £160 per annum; must be capable, energetic, good grower, usual class stuff shop and markets; fullest details of experience, age, references; good trade men only need apply.—K., Box 16, 41, Wellington Street, Covent Garden, W.C 2.

WANTED, FOREMAN, with good general knowledge of Nursery Stock, including Fruit Trees, Forest Trees, Roses, Shrubs, &c.; house, with garden, on premises. State wages required, with references.—JOHN PERKINS & SON, Billing Road Nurseries, Northampton.

WANTED, WORKING FOREMAN, for Rose and Fruit Nursery; also Second Man; must be good Knife Men; state wages and experience.—HEATH NURSERY CO., South Kilworth, Rugby.

WANTED, energetic WORKING FOREMAN (Outside), with good general knowledge of Nursery work, Trees, Shrubs, Roses, &c.—Apply, with copies of discharge, ARTHUR S. RITCHIE & CO., Belfast.

TOMATO and CUCUMBER GROWER wanted at once, to take charge of Nursery where Tomatos, Cucumbers, Bedding Stuff, and Chrysanthemums are grown.—Apply, stating full particulars, also wages required, "SURREY," Box 9, 41, Wellington Street, Covent Garden, W.C. 2.

TOMATO GROWER wanted at once; experienced in Indoor and Outdoor work; salary and commission; permanent; 10 miles from London.—J. H., Box 27, 41, Wellington Street, Covent Garden, W.C. 2.

MANAGER or MANAGERESS required, with knowledge of Seeds and Plants; good wages. Apply, stating age, experience, and salary required, to WEBSTER, Nurseryman and Seedsman, 30, East Street, Chichester.

WANTED, MAN, with general knowledge of Nursery work (Outside), near London (16 miles); single preferred.—Apply, in first place, with references, experience, and wages expected, to F. G. WOOD, 161, Walworth Road, London, S.E 17.

SEED TRADE — Wanted, a CHARGE HAND: one who has a thorough knowledge of all Garden Seeds, Sundries, and Nursery Stock, and accustomed to a brisk counter trade.—Apply, with copies of discharges, to ARTHUR S. RITCHIE & CO., Belfast.

LADY ASSISTANT wanted for high-class Florists' and Fruiterers' Business; good saleswoman and experienced in wreath and general floral work; seaside town.—Send particulars of experience, references, and salary, to W. H., Box 22, 41, Wellington Street, Covent Garden, W.C. 2.

Let Ryders Stock your Kitchen Garden.

Food prices have shown very little decrease. It is just as important as ever to sow Ryders Seeds in the garden or allotment and thus assure yourself of ample supplies of vegetables of quality and freshness.

Ryders have been preparing for many months in order to be able to offer comprehensive stocks of the world's finest seeds.

Experience has taught hundreds of thousands of gardeners and allotmenteers that it is wise to "Rely on Ryders," and the demand for Ryders Seeds, enormous as it has been, will be greater than ever this season.

RYDERS SEEDS

still at $1\frac{1}{2}$d. per packet.

Send for a Copy of Ryders Catalogue now.

It is a publication which no cultivator can afford to miss. You will find in it full particulars of **RYDERS 1919 VEGETABLE COMPETITION.** Last season's Competition was an enormous success. This season there will be Three Cash awards in each Class.

LEAF SPOT OF ORCHIDS.

IN his "Notes from Kew—XI." (*Gard. Chron.*, p. 224, Vol. XLIV.), *W. W.* drew attention to "Orchid Spot," and quoted the results of examinations of diseased plants made by the late George Massee, the late Professor Marshall Ward, and myself. May I say that the conclusion to which I came—and this surely is also true of Ward and Massee—referred solely to the particular specimens examined, and must not be accepted as applicable to all those diseased areas on Orchid leaves which horticulturists lump together as "Orchid Spot." "Orchid Spot" is not a single and specific disease, but a congeries of diseases, all little understood, and most urgently in need of detailed investigation. During the past two or three years I have had the opportunity of examining from time to time specimens of such diseased plants, and although no special attention has been given to this subject, a few observations and notes have been made, and a brief synthesis of these may, perhaps, prove to be not without interest to Orchid growers.

One of the most common forms of the disease is that described by Massee in *Diseases of Cultivated Plants and Trees.* It is characterised by small, pale, straw-coloured spots of irregular shape on the upper surface of the leaves, which, in the course of twenty-four hours or so, increase to from a quarter to half an inch in diameter, become somewhat sunken, and brown to purple in colour, and finally show right through to the underside of the leaves. The diseased area ultimately shrivels and dries, never, however, actually falling out to give a shot hole effect. During the early stages the cells contain large, oleaginous globules and much tannin, but these contents rapidly become discoloured and obscured by the brownish-purple disintegration products of the dead protoplasm. Not infrequently, in the later stages, various saprophytic bacteria invade these necrotic areas. As shown by Massee, and as may easily be confirmed by those sufficiently interested, this type of leaf injury is entirely a result of unsuitable cultural treatment, and may readily be reproduced under the specific conditions described in Massee's handbook. Local chilling of cells below the limit of their resistance, so that the physiological balance of the protoplasm is thrown out of gear, is the fundamental cause, and this chilling is most usually produced by spraying with water of too low a temperature. In many cases also this leaf spot is undoubtedly produced by the dripping of condensed water from the cool glass roof of the house upon the plants below.

There is much truth, therefore, in Massee's contention that this particular form of spot "does not require the attention of a plant pathologist, but the attention of a careful gardener who has some sense of proportion with respect to heat and moisture."

The fact that very young leaves are spotted equally with mature ones, is not infrequently brought forward as evidence that this disease is of an infectious nature, and due to the action of parasitic organisms. This, however, is not the case; the equal incidence of disease being a natural and inevitable result of the exposure of all leaves on the plant to the same unfavourable conditions. This particular disease, therefore, cannot spread in the absence of the specific environmental factors noted, and it will be equally evident that it cannot be prevented or checked by the most scrupulous cleanliness or rigorous sponging of the leaves, or by the spraying of the plants with any antiseptic solution.

An almost equally prevalent form of the spot disease is in general appearance almost identical with that described above, but the areas of dead tissues are rarely more than one quarter of an inch in diameter, are more regularly circular in form, and are not so sharply defined at their periphery. This is the type of leaf spot examined by me, the result of which is quoted by *W. W.* in the article already referred to.

Many of the cells about the middle of the blotch contain an amorphous granular deposit which chemically appears to be not unlike the colouring matter indigo. These individual cells and all those immediately contiguous are dead, but with increasing radial distance the tissues become progressively more healthy, merging almost imperceptibly into normally functioning cells. With the common exception that there is no zone of growth stimulation at the periphery, these spots present all the symptoms usually associated with local tissue poisoning. It may be that this poisoning is the result of some nutritive factor; but it would seem more probable that it is the effect of atmospheric pollution. As noted by *W. W.*, this trouble appears to be most prevalent in collections in or near large towns, and it is well known that many Orchids are peculiarly susceptible to the presence in the atmosphere of minute quantities of deleterious substances. If this explanation be correct one would expect these spots to centre in the stomata of the leaf where the gaseous exchanges occur, but at present there is no evidence on this point.

In the checking of this trouble it will be evident that neither antiseptic treatment nor attention to the common hygienic factors affecting the plant's health will be of avail, and the only method—and this, perhaps, hardly feasible—would be the chemical filtration of the air admitted to the houses. Perhaps when the inevitable steps are taken to prevent the wasteful and vile pollution of our atmosphere by the belching forth of smoke and chemical fumes, Orchid growers may see this trouble vanish from their plants.

Both the types of injury above described appear to be common to practically all the more usually grown species of Orchids.

A third type of leaf spot, and one of which I have had no personal experience, is said by Massee to be caused on the leaves of Cymbidium eburneum by the fungus Hypodermium orchidearum, Cke. and Mass. The spots are described as arranged in groups, often extending for a distance of one or two inches, and at these points the leaf turns yellow and dies.

On the leaves of species of Oncidium, Dendrobium, Coelogyne and other unidentified Orchids an olive-green blotching which later often turns brownish-purple, is not rarely seen, and this is caused by a species of Cladosporium, which may be the C. orchidis of Cooke and Massee, although morphologically it does not appear to differ from the ubiquitous C. herbarum, Link. The fungus grows well in pure culture, but no actual inoculation experiments have been carried out with it. Spores, however, taken from the tufts of conidiophores on diseased leaves and placed directly under the raised epidermis of healthy ones have in every case reproduced the disease.

For both of the above diseases sponging the leaves with a dilute solution of potassium permanganate has been recommended by Massee.

A leaf spot of many species of Orchid is not infrequently caused by the fungus Botrytis cinerea, Pers., one of the most common and destructive fungi in glass houses. The flowers are usually involved, and often the plant is killed outright, but occasionally the parasite is confined to local areas on the leaves, where, as in the classical case of diseased Lilies examined by Marshall Ward, moist, brown, sunken lesions are produced. The fungus grows with great readiness in pure culture, and the disease can be reproduced at will in healthy leaves.

The best general treatment for Botrytis disease is to sponge or spray the plants with a 3 to 4 per cent. solution of calcium bisulphate, and this treatment might be tried as a tentative expedient in Orchid houses where this fungus is present. It should also be borne in mind that where a glass-house is infected with pathogenic fungi the most rigorous cleanliness of the plants and cool freshness of atmosphere are imperative, as well as the immediate removal and destruction by burning of every fragment of diseased material. After touching diseased plants the hands should always be washed in soapy water.

Two other types of disease have been frequently noted differing from those described above, but included under the term "Orchid Spot" as used by horticulturists.

Of these, one is characterised by the presence of a series of concentric alternating zones of green to pale straw colour, and brown through purple to black. In these spots, which may vary in diameter from one-eighth of an inch with one ring, to one and a-half inch with many rings, the alternating zones are sharply defined, and may either be complete circles or segments of circles. On examination the deeply coloured zones of tissue are found to contain empty sporangia of a fungus probably belonging to the Chytridiales, a group of lowly organisms, which contains many important parasitic forms. Attempts made to grow this fungus in pure culture completely failed, and it was not further identified. Fragments of tissue taken from the outermost ring of a diseased spot and inserted under the raised epidermis of healthy leaves in most cases reproduced the disease. These spots are remarkably free from bacteria, and there is little doubt that the organism observed is directly responsible for their occurrence.

The very characteristic zonation of the diseased areas is probably correlated with the alternating vegetative and reproductive activity of the fungus. Many organisms are restricted in growth by the toxic products of their own metabolism, and in such circumstances either die out or form highly resistant reproductive bodies which serve to tide the organism over the period of adverse conditions.

In the case of the particular Orchid fungus the toxic products limiting vegetative growth and stimulating reproductive activity would after a time tend to diffuse away through the surrounding host tissues, and the sporangia would then be free to liberate their swarm-spores and spread centrifugally until again checked by the accumulation of toxic substances.

This type of disease has been noted on species of Odontoglossum, Cattleya, Dendrobium and other undetermined species, and is probably spread by splashing and the dripping of water from leaf to leaf, and by the touching of healthy plants when diseased ones have been handled.

In the last type of "Orchid Spot" to be described the symptoms are more or less intermediate between the above noted zonal necrotic areas and the simple blotch of the earlier cases. Beginning as a minute straw-coloured spot which later turns purple or deep brown, there is at first a tendency to a rather diffuse zonation, but the segments soon become joined into an anastomosing pattern by short, irregular, purple radii. The latter spread tangentially until a streaky blotch results, the diameter of which may reach to about three-quarters of an inch.

No special features in the cell-contents may be recognised, the discoloured tissues merely containing the products of the autolytic disintegration of the protoplasm. In the young stages of the disease no organisms of any kind appear to be present, but later various saprophytic bacteria often invade the tissues. Some of these were obtained in pure culture, but failed to reproduce the disease when inoculated into healthy leaves. Fragments of diseased tissues inserted under the raised epidermis of healthy leaves gave a like negative result.

Examination of these leaf blotches leaves one strongly with the impression that parasitic organisms are not concerned in their initiation. There are no symptoms such as usually accompany local poisoning of plant tissues. It would seem most probable that they are the result of some unfavourable cultural factor. This type of "Orchid Spot" has been found in species of Masdevallia, Cattleya, Laelia, Zygopetalum and other but unidentified Orchid leaves.

Thus in the casual examination of "Orchid Spot" as specimens have from time to time come to my notice, seven distinct types of disease have been recognised. Of these it is highly probable that four are the result of the action of parasitic organisms, one of local chilling of the leaf-tissues, one probably of atmospheric poisoning, and one of some other physiological derangement of the protoplasm, due probably to unsuitable cultural conditions in the plant's physical environment.

There can be no doubt that a continuous and intensive study of "Orchid Spot" would show that the seven diseases noted are but a few of the many covered by this name

It is the lack of the recognition of the complexity of plant disease which leads to one half the difficulties experienced by "irate correspondents" in their cultivation of Orchids and other plants. Often on one and the same plant two or more quite distinct types of disease may be present, both with almost identical symptoms, or in an infected house one diseased plant may be submitted for scientific advice whilst in reality the majority of the plants may be suffering from an apparently similar disease of totally different nature. At present all these diseases are lumped together as "Orchid Spot," and horticulturists endeavour to control a disease of physical causation by a fungicidal spray; or a fungal epidemic by regulating to a nicety the temperature of the water supply.

What is really needed is a detailed and intensive investigation of this group of diseases; a patient and critical experimental study of the fundamental physiological relations of the plants to their environment; an understanding of all the complex hygienic factors involved; and a thorough elucidation of the life histories and biological relations of the pathogenic organisms which may be present. Only on such a foundation can a rational scheme of prophylactic and therapeutic treatment be based.

In this country the little recognition given to the study of disease in plants, and the lack of facilities for effective research in the specific diseases of horticultural plants, has greatly impeded progress in this direction. It is to be hoped that the newly-formed Chamber of Horticulture will, amongst its many activities, accord due place to this most important study, and encourage and insist that opportunity be provided for the scientific investigation which is so imperative if the problems of disease in plants are to be solved. *William B. Brierley, Institute of Phytopathological Research, Rothamsted Experimental Station, Harpenden.*

Fig. 22.—Crocus Imperati: flowers striped with reddish-purple.

BULB GARDEN.

CROCUS IMPERATI.

The sketch reproduced in fig. 22 represents Crocus Imperati as it flowers here in the open in the first week of January. C. Imperati is surely one of the most desirable of the winter-flowering species, for its hardiness, for the richness of its colouring, and for its large, sturdy flowers of such substance that they seem able to endure the roughest of weather. Though in some forms the segments are almost entirely unveined, in the typical form the veins are very strongly marked on the three outer petals. There are three main veins on each petal, with more delicate featherings springing from them. The central vein is continued as a dark stripe down the tube, which has six dark stripes on a pale ground, for the central stripe of the three that are found on the lower half of each of the inner petals is also continued down the tube. The stripes are of the deepest red-purple, and the ground colour of the outside of the outer petals is either a greyish white or a pale buff. In quick response to any gleams of sunshine, the outer petals begin to unfold, and then display the reddish mauve of the inner segments and of their own inner surface. The contrast of colour is very striking, and, if the weather is too dull and cold for the flowers to open, it will be found that they will respond rapidly to warmth and artificial light indoors. When the flowers are fully expanded, they display their orange throats and the deep bright orange of the broad stigma, which scarcely overtops the yellow anthers. There are many colour-forms of this Crocus, and an albino with creamy-white flowers, that comes true from seed and has a good constitution. With me, it seems to flower a week or more later than the coloured forms.

It is strange that Maw should have had this Crocus in flower in March and April. At any rate, these are the dates at which his drawings were made, though in the text he gives February as the flowering season. The foliage of C. Imperati is characteristic in that it tends to sprawl widely on the surface of the ground and seldom stands erect.

Crocus Imperati appears to be found only in a comparatively limited area in the South of Italy, for it does not extend far to the north of the neighbourhood of Naples. *W. R. Dykes, Charterhouse, Godalming.*

ORCHID NOTES AND GLEANINGS.

ODONTIODA NORMA.

Mr. Pantia Ralli has sent an eight-flowered inflorescence of this delicately-tinted novelty raised between Odontioda Lutetia (Cochlioda Noezliana × Odm. luteo-purpureum). It is a very desirable hybrid, with colouring which will appeal to all artistic tastes. The flowers are as large as, and formed like, the best type of Odontoglossum crispum; the ground colour is primrose-yellow, the inner halves of the segments bearing irregularly ovate blotches of a delicate reddish-orange tint. The labellum bears distinct evidence of O. luteo-purpureum in the form of the yellow crest, around which are several brownish-red blotches.

Odontioda Lutetia has never been considered a hybrid of the front rank, but in this, as in some other cases which we have noted, the influence of O. luteo-purpureum has given remarkably good results.

ODONTOGLOSSUM LA VICTOIRE.

From Messrs. Sanders, St. Albans, we have received the seven-flowered upper part of a fine spike of this very extraordinary hybrid, which appears to have all the desired floral perfections and unique colouring, with the following remarks: "We are sending you part of a spike of a most magnificent new Odontoglossum, which is the first we have had over from Bruges for

four and a-half years. Our Mr. Louis Sander brought it back with him. We have named it La Victoire, and consider it quite one of the best we have ever seen. In colour we know none like it."

The remarks are fully justified, and the flowers, closely arranged on the spike, are nearly 4 inches across. All the segments are equally broad, and coloured bright claret with a ruby-red glow over the surface. The colour extends through the substance of the flower, the white ground only appearing slightly on the toothed margins of the petals, in a small area at their bases, and on the margin of the lip. The upper side of the column is claret colour. It is one of the finest proofs of the utility of the work of the hybridist, for no known species or combination could be expected to give such richness of colour.

BRASSO-CATTLEYA GATTON LILY.

This hybrid between B.-C. Digbyano-Mendelii var. Fortuna, a white variety, with a slight green shade, and Cattleya Trianae albens, for which Sir Jeremiah Colman, Bart., Gatton Park, Surrey (gr. Mr. J. Collier), was awarded a First-class Certificate at the meeting of the Royal Horticultural Society on Dec. 3, 1918, is a welcome addition to a favourite class, and all the more desirable in that it departs from the over represented general run of Brasso-Cattleyas with flowers of shades of pink and pale rose, and approaches nearer to the distinct B.-C. Cliftonii class, which also has C. Trianae as one of its parents. The introduction of C. Trianae albens, the second of the C. labiata section, into its composition, has given a much more Cattleya-like form to the flower, and extraordinary breadth of petal. The flowers are pure white, the lip having a veined band of violet colour in front and a pale yellow disc.

TREES AND SHRUBS.

CUPRESSUS FUNEBRIS.

With reference to notes that have appeared in recent numbers of the *Gardeners' Chronicle* regarding the production of cones by Cupressus funebris, a tree that was planted by Lord Granville, in the grounds at Walmer Castle, Kent, in 1868, produces cones freely. The tree is 30 feet high, with a branch-spread of 18 feet, the stem girthing 2 feet 7 inches at a yard from the ground. This tree is of particular interest to readers of the *Gardeners' Chronicle* as having been supplied from his nursery at Canterbury by the father of Dr. Maxwell T. Masters, formerly Editor of this paper, and the recognised authority on Coniferous trees. Unfortunately, Cupressus funebris is not to be depended on everywhere in this country, the best developed specimens being in the milder parts of England, and generally in maritime districts.

When seen at its best Cupressus funebris is a tree of unsurpassed beauty, the beautiful, weeping branchlets hanging gracefully downwards for fully 2 feet in length (see fig. 23). Cones are produced in great abundance, and the delicious aromatic fragrance of the foliage is well known to those who are familiar with the tree.

Specimens of Cupressus funebris are rare, the finest I know being that beside the Grand Lodge at Penrhyn Castle, in Wales, and on the lawn at Churchill, in the North of Ireland, where, in the latter case, it is accompanied by a 40 feet high tree of the equally rare and beautiful C. Goveniana.

Another of Masters' trees is growing in the neighbourhood of Walmer, a probably unique specimen of the weeping Maidenhair tree (Ginkgo biloba pendula), which is 28 feet high, with a branch spread 30 feet in diameter, the main stems, for there are two, girthing 4 feet 2 inches and 3 feet 10 inches respectively, at a yard from the ground level. In every respect this is a perfect tree, being well furnished with branches, the tips of which hang downwards for, in some instances, a distance of 4 feet, thus imparting an easy and graceful appearance to this otherwise somewhat stiff-styled Conifer. A full account of these trees will be found in *Coniferous Trees, for Profit and Ornament. A. D. Webster.*

TILIA TOMENTOSA.

As this species flowers quite two weeks later than Tilia vulgaris, the common Lime, it is extremely useful for prolonging the season during which bees can obtain honey, and should be included in all new plantations of forest trees. I am informed that the tree is plentiful on the Continent, but in England it has not received the attention its merits deserve, and in many districts it is absent altogether. The largest specimen I have seen is in the beautiful cemetery at Coventry, which was designed by the late Sir Joseph Paxton. This tree measures 7 feet 8 inches in circumference of the stem at 3 feet above the ground, and I estimated its height to be nearly 60 feet. There are many smaller trees of this Lime, and a good collection of Conifers and other trees at Coventry that have grown into good specimens, but now need judicious thinning and to have Ivy cleared from them. Nicholson's invaluable *Dictionary of Gardening* gives T. alba as a synonym of T. argentea, which is now referred to T. tomentosa; both names were evidently suggested by the silvery whiteness of the underside of the leaf, which is much larger than in the common Lime tree. *W. H. Divers, Westdean, Hook, near Surbiton.*

Fig. 23.—Branch of Cupressus funebris with cones.

MUSTARD-GROWING AS A PREVENTIVE OF WIREWORM.

FOR many years the cultivation of White Mustard has been recommended as one of the best methods of dealing with land infested by wireworms, and since there seem to be some doubts both as to the results which may be expected from the treatment and the manner in which it is carried out, a few notes on the subject may be of interest.

Dealing with the latter question first, the Mustard crop may be treated in three ways: (1) It may be grown as a seed crop, in which case it will be sown in April-May, and will occupy the ground for the whole summer; (2) it may be ploughed in green, usually when about 18 inches to 2 feet in height; (3) it may be eaten off by sheep. In the two last cases the Mustard is usually sown in late summer, after a fallow, or when an early crop has been harvested.

The three methods clearly differ in principle with regard to their influence on the soil, for in the first there is no manurial benefit, and comparatively little of the Mustard plant is left in the ground. In the second and third methods the manurial effect is considerable, but again there is a difference, for in the second the entire Mustard plant is turned under, while in the third the greater part is eaten by the sheep, and there are both the manurial and the trampling (and, in consequence, consolidating) effects of the animals to be considered. Strange to say, each of these methods is recommended almost impartially for wireworm-infested land, the choice being guided mainly by local custom—i.e., where Mustard is usually grown for seed, this method is favoured; in other districts, either the ploughing in or feeding off are more usual.

I come next to the evidence in favour of Mustard-growing as a preventive of wireworm. It must be admitted that there is little direct experimental evidence, and almost the whole of our information has been derived from practical experience on the farm. At the same time this experience has now extended over so many years (successful trials were recorded at the beginning of last century), and has been so greatly in favour of the system, that it may safely be concluded that Mustard-growing does tend to rid infested land of wireworms. It is impossible in a short space to quote many definite cases in support of this view, but the writer's own experience in connection with a farm in the East of England may be of interest. On this farm grasses have been grown for seed for many years, and these grass leys at the end of their term are always so infested with wireworms that when they are broken it is difficult to grow any crop upon them. This difficulty, however, is almost always overcome by growing a first crop of Mustard for seed, with the result that the crop following the Mustard is seldom damaged. The Mustard crop itself usually escapes all injury, but once it suffered considerably. In this case, for reasons which need not be entered into, the grass sods were burnt in early spring instead of being turned under. The field was then absolutely clean, but full of wireworms, and on Mustard being sown, about half the crop was lost by wireworm attack, the pests burrowing into the stems of the Mustard and killing the plants, even when they had grown to some size. After the Mustard crop was harvested, few wireworms could be found in the field; Wheat was sown, and an excellent crop resulted. This case is instructive, and leads to the consideration of what may be the effects of Mustard on the wireworms. In the first place, general experience shows that Mustard is seldom attacked, but at the same time it is clear that when the wireworms have absolutely no other food, they can for a time eat Mustard. Equally, however, it seems that they cannot flourish on Mustard, and if there is little else growing on the land during the summer they gradually die out.

This seems to give some explanation of the effect of the Mustard seed crop, but the ploughing in or feeding off present more difficult problems. The crop then is not on the ground for long, and the partial starvation of the wireworms can hardly occur. In the case of sheep feeding, the thorough trampling and manuring by the sheep is doubtless unfavourable to wireworms underneath, but where the Mustard is ploughed in it would almost appear as if the plant on decomposition released some substance (Mustard oils?) definitely injurious to wireworms. At this point it seems wise to leave speculation on the subject, since wireworms are being fully investigated at Rothamsted Experimental Station, and definite facts may be forthcoming.

The above observations have, perhaps, been made rather from the farmer's point of view, since it is on the farm that Mustard-growing is carried on; but, in conclusion, it may be well to suggest their application in the case of the horticulturist and gardener. In the first place, Mustard growing is a preventive measure. It would be useless, for instance, to grow Mustard among Potatos to protect the latter. If this were done, there would either be no effect, or the wireworms might even be driven to the Potatos, for it is quite clear that wireworms will not eat Mustard if they can get anything else. If Mustard is to be used by the gardener as a treatment for wireworm, probably the best method of so doing is to sow it as a first crop, preferably for seed, on land which is afterwards to be divided into allotments or gardens. It will

FIG. 24.—CLICK BEETLE AND ITS LARVAE, THE WIREWORM.

enable the land to be thoroughly cleaned of weeds, and, apart from its effects on wireworms, will certainly prevent subsequent trouble from such "annual" pests as leather jackets. Nothing is so troublesome to the allotment holder as to find his plot infested by wireworms and other soil pests, and the loss of a year's crop of vegetables would probably be amply compensated by a relative freedom from injury subsequently. When the land is already garden or allotment, then Mustard is well worth growing to be dug in as a green manure. Its value for this purpose alone is worth the trouble and expense, while there is also the general experience that wireworms will be much reduced.

On the whole, the practice of growing Mustard on wireworm-infested land seems much to be commended, although from the scientific point of view its effects on the wireworms are still rather obscure. *T. C. F. Fryer, Board of Agriculture.*

SUNFLOWERS FOR SEED.

LAST year I grew one acre of Sunflowers; half the seed was sown in boxes in cold frames, and the remainder sown in the open. The former batch was much the more successful; the fully-matured heads were cut in September, and when fully ripened the seeds were taken out, crushed, and fed to the fowls with other food.

I think so little of the crop that I shall not extend it; indeed, I prefer to fill the plot with early or late Drumhead Cabbage. *E. M.*

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Digging and Trenching.—When weather permits, digging and trenching should be proceeded with as rapidly as possible, and manure suitable for the crops added to the ground. The soil that is brought to the surface will receive the full benefit derivable from exposure to those winds and frosts that invariably visit us before seed sowing and planting become general.

Peas.—Peas sown in pots during the autumn for the purpose of securing a crop under glass must be encouraged in every way, but fire-heat should not be used except in very severe weather. The plants will now need a light top-dressing composed of equal parts of Mushroom bed manure and loam. Give them the necessary staking, afford an abundance of air during favourable weather, and syringe and close the house early each afternoon to husband the sun-heat.

Peas Out-of-Doors.—A sowing of Peas should now be made out-of-doors on a border facing south. Sow the seeds in trenches made with a 9-inch draw hoe, to the depth of 4 inches; sow thinly, and cover the seeds with about 2 inches of soil, thus leaving the trench level two or more inches lower than the surrounding soil, and so providing shelter for the seedlings from keen winds. Should the soil be sticky, cover the seeds with old potting soil. Early Giant, Early Morn, and The Pilot are splendid varieties for early sowings.

Parsley.—Every endeavour should be made to maintain a constant supply of Parsley. For early summer supplies seeds should now be sown in boxes placed in gentle heat. When large enough to handle prick out the seedlings at 2 inches apart into other boxes. Gradually harden them off, and plant out at 12 inches apart during April in well prepared ground. Plants furnishing the present supply of Parsley, whether in frames or in the open, should have every encouragement; stir the surface soil and give frequent light dressings of soot.

Asparagus.—Where the maincrop Asparagus beds have not been top-dressed this should be done forthwith. Clear weeds from the surface of the beds and apply a dressing of manure.

Spinach.—Good Spinach is always welcome, but the uncertainty of the weather during the next two months prompts one to sow seeds in one or two lights on a gentle hot-bed. The autumn sown out door beds need to be regularly hoed, and frequently dusted with soot and wood ash. A few boughs of Spruce or Yew help to protect this crop if placed on the northern side of the beds.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Disa.—The genus Disa includes some of the most beautiful terrestrial Orchids in cultivation, and yet it is extremely rare to meet with plants in good or even presentable condition, hence they are not generally grown. Their season of growth is during winter—a period of the year when most cultivators dislike soaking a plant with water. The plants grow best in a cool, moist, airy position, in a house having a minimum winter temperature of 40° to 45°, but they must be well supplied with water. They grow well in compost formed of peat and Sphagnum-moss, with the addition of a little coarse silver sand, and I have seen them growing vigorously in a compost to which a portion of fibrous loam has been added, but the pan in which the plants are grown must be thoroughly well drained, or the compost will speedily become unsuitable. The chief details in the successful cultivation of these Orchids are a cool temperature, a shady position, good drainage, and an ample supply of water.

Cypripedium.—No Orchid flowers are more serviceable, both on the plant and as cut blooms, than those of late autumn and winter-flowering Cypripediums. The flowers remain fresh on the plants for many weeks in succession, and they keep surprisingly well when cut and placed in water, provided they are not unduly exposed to dry heat or to cold draughts. Plants in bloom may be kept for a short period in a dwelling-house without suffering thereby. To these excellent qualities, moreover, must be added another, viz., their power of withstanding town fogs, which they resist perhaps better than any other Orchids in cultivation. Winter flowers have a special charm, and, as the numerous varieties of Cypripedium now in cultivation are of great beauty, and conspicuous for their colouring and splendid form, the Lady's Slipper Orchids should be extensively grown in large private gardens where quantities of flowering plants are needed for house and conservatory decoration. It may be said that they are expensive, and this is true of the rarer hybrids, but many beautiful forms may be obtained at almost the prices paid for Pelargoniums. C. insigne, in its remarkable and varied forms, and the numerous varieties of such hybrids as C. Leeanum, C. nitens, C. Calypso, C. Euryades and C. Actaeus, that have originated from C. insigne, are cheap plants comprising some of the most useful and easily accommodated of the whole genus. Their requirements are such as can be afforded by anyone in possession of a greenhouse in which an intermediate temperature can be maintained. A minimum night temperature of 50°, ranging to 80° by day in bright summer weather, is suitable for these plants. Shading is a very important detail in their successful cultivation: an excessively dense shade will result in wonderful leafage, but the flowers such plants produce are seldom of the best quality. Much depends in this respect on the position of the house, but whatever the aspect, plants grown under moderate shading—sufficient only to keep bright sunshine from striking on the leaves—if air is properly admitted, will have foliage firm in texture, and be thus able to produce fine flowers in abundance.

PLANTS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the Duke of BUCCLEUCH, Dalkeith Palace, Midlothian.

Flowering Plants.—Where Bouvardias have been grown in an intermediate temperature during winter they should be cut back after flowering and placed in a warmer position near the roof-glass and syringed daily, so that strong, healthy cuttings may be obtained quickly. Plumbago rosea is a most useful winter-flowering plant, requiring a temperature of 60°; when the plants have finished flowering shake the soil from the roots of a few specimens, cut the roots into small pieces, and place them in pans of soil plunged in bottom heat. These cuttings will provide useful plants for next winter. Poinsettias that have served their purpose should be gradually dried off and kept at rest in a cool house for a time; afterwards cut them back hardly and place them near the roof glass in a warm house, where they will make new growths suitable for cuttings. Begonia Gloire de Lorraine when flowering is over should be partially cut down, rested for a time, and kept clean and healthy until they make growth, when cuttings may be taken, put into well drained pots or pans and placed on a stage or shelf near the roof glass. Tuberous rooted Begonias are most useful for greenhouse or conservatory decoration in summer: the tubers may now be placed in ordinary propagating boxes filled with a mixture of soil and leaf mould. Put the boxes on a stage in a warm house, spray the tubers occasionally, and when growth commences place them in their flowering pots.

Gloxinias.—The most economical way of starting Gloxinia tubers into growth is to place them in propagating boxes. Put a layer of leaves over the bottom of the box, and then fill with a light mixture of loam, peat, and sand. The surface of the tubers should not be covered with soil, and the soil should be fairly moist. An overhead spraying will provide sufficient water for them until growth has advanced a little. Afford a temperature of 60°, and later on pot the tubers according to their size into 5½ or 6½-inch pots; pot firmly in a compost of fibrous loam, peat, leaf-mould, sand and charcoal. Stand the plants near the glass in a warm house and water carefully. Gloxinia seed sown now will provide plants for flowering in the autumn; drain shallow pans, fill them with finely sifted soil, peat, and sand, and make the surface level before sowing the seed; thoroughly soak the soil with water, and sow the seed on the smooth surface. No covering of soil is necessary if the pans are placed in a warm propagating case and covered with paper until germination occurs.

FRUITS UNDER GLASS.

By W. MESSENGER, Gardener to C. H. BERNERS, Esq., Woolverstone Park Gardens, Ipswich.

Strawberries.—The earliest forced Strawberry plants will soon be in flower, and when this critical stage is reached advantage should be taken of fine days to distribute the pollen over the principal blossoms. This may be done with a soft, feather brush. The conditions most favourable to perfect setting of the fruits are an elevated position on shelves near the roof glass, a moderately dry atmosphere, a liberal supply of fresh air, and comparatively dry condition at the roots. A temperature of 50° to 55° by night and 65° on sunny days will suffice for the plants whilst in flower. A fresh batch of plants may be introduced into the forcing-house, according to requirements.

Vine Eyes.—The method of raising young vines from eyes is the one adopted generally. From well-ripened growths laid in at pruning time, select the soundest buds, cut them out with about half an inch of wood on either side, and insert them in small 60-size pots filled with fibrous loam, leaf-mould and sand. Place the pots in a warm house for a few days before plunging them in a hotbed of about 75°.

Cucumbers.—Where provision has been made for a successional crop, the winter fruiting Cucumbers will not be worth retaining after another few weeks. To encourage growth afford occasional supplies of weak liquid manure, or some approved chemical stimulant. Thin the growths sufficiently to prevent overcrowding, and pinch the laterals at the second leaf. Maintain a moist atmosphere by damping down the house several times a day and syringing the plants when the weather is favourable. Little or no air should be given at this season of the year. Afford a minimum night temperature of 60°, and a day temperature of 70°, allowing a rise of 10° to 15° with sun heat. Young plants which are forward enough may be put into their fruiting quarters. A hot-bed should be made up as advised for Melons, building up the bed as near to the glass as convenient. A suitable compost will consist of light fibrous loam, leaf-mould, and a good sprinkling of wood ash.

Pines.—Plants of the Queen variety likely to produce fruit during the spring should be top-dressed at once. Remove a few of the old leaves at the base of the plant and the old surface soil, and top-dress with good turfy loam and bone meal. If the soil is dry afford sufficient water at a temperature of 80° to thoroughly moisten it down to the crocks, after which very little water will be required for some time to come. A temperature of 70° by night and 75° to 80° by day, with a bottom heat of from 80° to 85°, will suit the fruiting stock. During severe weather a slight fall in the temperature may be allowed with beneficial effect on the plants. The bottom heat should not exceed 85°; should it do so slightly rock the plants to and fro, so as to create a free air space round the pots.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Cherry Trees.—Dessert varieties of Cherry mostly fruit on spurs. Very little pruning will be required if the shoots were shortened last summer. Where this was not done, they should now be shortened to about 2 or 3 inches, and all weak shoots removed.

Blackberries.—These useful fruits are often neglected, yet they well repay for good cultivation. The method I adopt is to cut out all old wood as soon as the fruit is gathered, and train in young shoots, about 9 feet long, in a slanting direction; any growth beyond this is allowed to remain until the spring, when it is shortened to the top of the trellis, which is 6 feet high. Sand and cold clays do not suit the Blackberry, which enjoys plenty of water and a free drainage. Plants making gross growth are improved by having a spade inserted the full length of the blade in the soil around them. The various kinds of Brambles are easily propagated by notching and pegging down the young shoots. Loganberries may be treated similarly.

Loam for Next Year's Use.—Owing to continued wet weather the condition of the pastures has not been suitable for cutting a supply of turf for stacking, but it should be done as soon as the land is sufficiently dry. Select the turves from an old pasture in order to obtain plenty of fibre in the material. In stacking the turves spread one row turf-side downwards and then sprinkle it with a little lime and crushed bones; add another layer of turves and sprinkle more lime and bones, and continue in this way until the heap is complete. If the turf is not of very rich quality use a layer of well-decayed manure between the turves, or between alternate rows. The centre of the heap should be raised. When the stack is completed it should be protected from heavy rains by boards or sheets of galvanised iron. The compost should be in splendid condition for use by next autumn, when the heap should be chopped straight through from top to bottom. In some districts excellent turves may be obtained from the roadsides, especially where the metal used for making the road contains iron or lime. In some districts the roads are sprayed with tar, and care must be taken not to use sods that have been sprinkled with tar. The thickness of the turves will depend on the quality of the soil and depth of fibre, and may vary from 2 to 5 inches.

THE FLOWER GARDEN.

By H. MARKHAM, Gardener to the Earl of STRAFFORD, Wrotham Park, Barnet, Hertfordshire.

Herbaceous Borders.—February is a busy month in the flower garden when much planting, alteration, and making of new herbaceous borders remains to be done. Those who intend to make fresh beds should lose no time before getting the soil well trenched, manured, and put in perfect order for the reception of the plants. If the beds are to be in groups prepare a plan of planting in order that a colour scheme may be arranged. Numerous hardy flowers may be increased by division. Select healthy portions from the sides of the old stools and plant them with due consideration as to height, colour, and season of flowering. Should the soil be very damp and sticky employ a little prepared material about the roots before pressing them into the ground firmly.

Anemone.—If the tubers of Anemone fulgens have not been planted set them forthwith, 3 inches deep and about 6 inches apart, in beds well enriched with decayed manure and rendered porous by the addition of grit. With reasonable attention in keeping the beds free from weeds and the surface lightly pricked up occasionally, the plants should provide a good display of flowers in spring. The merits of A. coronaria should not be overlooked as a spring flower. There are varieties of pleasing colours that will make a good show if planted early.

Antirrhinum.—If suitable accommodation is provided for raising Antirrhinum plants from seed the latter should be sown now if the plants are intended to bloom during the forthcoming season. It is an easy matter to select from among the many excellent varieties plants of tall, intermediate and dwarf habit. Sow the seed in clean, well-drained pans, covering the crocks with a little moss or tree-leaves. Fill the pan to within a couple of inches of the rim with sweet, rather lumpy compost, over which place some finer soil containing plenty of sand. Press the soil firmly, scatter the seeds evenly, cover them with similar soil, and gently press it down.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* Publisher; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* Editors. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Richmond Allotment Association, meet. and lecture, 8 p.m.

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.0°.

Actual Temperature:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, February 5, 10 a.m.: Bar. 29.8; temp. 33°. Weather—Snowy.

Rural Cottages from Army Huts. The Munitions Inventions Department, which has rendered such valuable service during the war in elaborating methods of destruction, has been prompt to seize the occasion offered by the armistice to turn its ingenuity to peaceful ends, and has designed and erected from standard hutting, used by the War Office and other departments, the cottage illustrated in fig. 25. Inasmuch as the housing problem is so acute that it is difficult to see how it can be solved in reasonable time, even though all the resources of the country are employed upon it, this example of reconstruction should prove particularly valuable. The cottage, which has been erected at Claremont Park, Esher, was designed by Capt. G. B. Imrie, R.E., for the Munitions Inventions Department, and, as inspection of the hut and of the plans shows, it makes a pleasing and commodious dwelling. There are evidently many advantages in the use of standard hutting for supplementing the supply of cottages. Among these advantages are, first, that the bulk of the materials, roof, exterior walls, windows and floors is ready for use, and hence time and labour will be saved. Second, the time taken in the erection of the hut is relatively short; the example at Esher was built in fourteen seven-hour days. Third, any local builder can effect the conversion and erection of the hut, and can produce a dry, warm, and sanitary dwelling. Fourth, the cost is relatively low: in the case of the Esher experiment the net cost of conversion and erection, exclusive of water supply, was just under one hundred pounds, reckoning materials and labour at present-day prices. Thus, assuming that the huts could be procured at a price of £10 per 10-foot section, delivered to the building site, the cost of a 40-foot standard hut of four sections would be £40, and the total cost of a four or five-roomed cottage about £140, a sum considerably less than that required for building a cottage. The plans in fig. 27 show two methods of conversion. In the one type, A, the cottage has four good rooms, and this is the type erected at Claremont Park. In type B there is an extra room, and the rooms generally are slightly smaller than in type A.

The cost of this latter type would be rather less than the former, owing to the fact that there are fewer partitions, and also that less plumbing is required. At a cost of an additional £20, an extra section can be used, and still better rooms obtained. If, after careful investigation, the authorities are convinced that satisfactory cottages can be made in this manner, it is to be hoped that arrangements may be made without delay for putting the standard hutting to this use. It should not be difficult to devise means whereby the hutting could be put at the disposal of local authorities and private owners for the purpose of building cottages in districts where they are particularly needed.

Fig. 25.—A COTTAGE MADE FROM ARMY STANDARD HUTTING.

Horticultural Club. — The annual general meeting of the members of the Horticultural Club will take place on Tuesday, the 11th inst., at 5.15 p.m., at Anderton's Hotel, Fleet Street. The President, Sir Frank Crisp, Bart., will take the chair. The meeting will be followed by the annual dinner, which will take place at 6 p.m. at the same place. After dinner there will be a musical programme.

Royal Horticultural Society's Examinations in 1919. — The Royal Horticultural Society's General Examination in Horticulture, senior and junior, will be held this year on Wednesday March 19. The Teachers' Preliminary Examination in School and Cottage Gardening will take place on Saturday, April 26, and the written part of the Honours Examination will be held on the same date, to be followed by an examination in practical work in June. For the Honours Examination candidates must fill in the form provided and send it with £3 3s. to the Secretary of the R.H.S. at least eight weeks before the examination takes place. The Society's Board of Examiners has decided to accept the Teachers' Certificate in Rural Science (including School Gardening), given by the Department of Agriculture and Technical Instruction for Ireland, in place of the Teachers' Preliminary Examination for candidates sitting for the Teachers' Honours Examination. The examination for the National Diploma in Horticulture will be held in September. Copies of the R.H.S. Examinations Syllabus may be obtained on application (enclosing 1½d stamp) to the Secretary, Vincent Square, Westminster.

Shrewsbury Floral Fête.—We regret to learn that the Shropshire Horticultural Society has been reluctantly compelled to abandon the exhibition it proposed to hold in 1919 because the railway companies have definitely decided that they are unable to grant the usual facilities.

Gift of a Public Park.—The Duke of Buccleuch has offered the town of Langholm the field of Eldinholm, close to the Parish Church, as a public park, together with the footbridge leading to it.

National Diploma in Horticulture. — The Royal Horticultural Society informs us that its Board of Examiners has determined that men who have been on active service for two years or more shall be allowed to enter for the Preliminary Examination for the National Diploma in Horticulture if they have had two years' experience in gardening, instead of the four years as required under Section 6 of the Syllabus;

and also that candidates who have done one year's military service need only have had three years' experience in horticulture under the same section.

Revival of the Yorkshire Gala.—The Grand Yorkshire Floral Fête and Gala will be held this year, and the dates fixed are June 18, 19 and 20. Like most of the large provincial flower shows, the York Gala has been suspended during the period of the war, the last exhibition having been held in 1914. We congratulate the committee on its decision to resume activities so promptly, and trust that the same splendid success will attend its efforts this year as in the past.

Fruit Growing.—About 10 acres of land at the Holbeach Crown Colony are to be laid out as a demonstration fruit plot. Demonstrations in the pruning of fruit trees have been given recently by experts of the Food Production Department at Aylesham and Harbeston (Norfolk), in the Kesteven district, and at Grantham (Lincs.) and other places.

Army Stable Manure.—An arrangement was made last year between the Food Production Department and the Army for the supply of Army manure to farmers and allotment holders in various parts of the country. A big dump near Aldershot has been distributed, partly by barges working on the Basingstoke canal. Under this scheme about 15,000 tons of manure were supplied to farmers and allotment holders of Surrey and Hampshire at 4s. 6d. per ton. It is stated that had this arrangement not been made a number of agriculturists, chiefly smallholders, would have been unable to get sufficient manure for their land.

Sulphate of Copper.—The Government does not propose to take steps to control the selling price of sulphate of copper this year. The supply available for agricultural and horticultural purposes is reported to be ample, and the necessity for control does not therefore arise.

Selected Seed Potatos.—The Board of Agriculture arranged last year for the growth of a certain quantity of seed of immune varieties of Potatos by Scottish growers. The crops were carefully "rogued" under the supervision of the Department's inspectors, and specially selected. They are being sold through agents in different parts of England and Wales, and a limited amount of seed remains on offer. The varieties represented are Ally, Lochar, Kerr's Pink, Dominion, Majestic, and Tinwald Perfection. Intending growers of Potatos in infected areas who have not yet secured their seed are advised to make early enquiries from the Commercial Secretary, Board of Agriculture, 72, Victoria Street, London, S.W. 1.

Honour for the Clerk of the Gardeners' Company.—Mr. E. A. Ebblewhite, clerk of the Worshipful Company of Gardeners, has been created Chevalier de l'Ordre de la Couronne by His Majesty the King of the Belgians in recognition of "the constant and generous help given to my country in the course of the war." The Foreign Office has intimated that warrants under the Royal Sign Manual, giving formal effect to the King's permission to wear the decoration, will be issued to Mr. Ebblewhite, who has been clerk of the Worshipful Company of Gardeners since 1903, and had already received the Décoration Agricôle Spéciale of the 1st Class by Royal Warrant of the King of the Belgians, dated February 19, 1914.

Revision of Pritzel.—The Rev. W. Wilks, secretary of the Royal Horticultural Society, writes: "I regret that a mistake has crept into the notice of the Pritzel revision which appears in our Report and is noticed in *Gard. Chron.*, January 25. It is quite true that Capt. Hill is taking the greatest possible interest in the revision, but it is to the Keeper of the Herbarium at Kew that we owe our chief thanks, as he is not only supervising the work as it proceeds, but has also most generously consented to act as Hon. Editor."

Brussels Botanic Gardens.—Major A. Simmonds, an old Wisley student, and at the outbreak of war Horticultural Instructor for the County of Hertfordshire, sends the following interesting letter from Brussels, dated January 17, 1919: "In response to a request from the citizens of Brussels to see a representative body of British troops, a review was held yesterday, when bodies of troops marched through the principal thoroughfares. The King of the Belgians, who was accompanied by the Prince of Wales and Prince Albert, reviewed the troops as they passed the Palais du Roi. As one of our companies went to represent the Machine Gun Corps I went into Brussels to see the parade, and whilst there made a point of looking up M. Louis Gentil. It was Sunday, and when I reached the Botanic Gardens I found that M. Gentil was at his house, some ten minutes' walk from the gardens. However, I easily found him, and immediately I introduced myself was greeted most cordially. M. Gentil was very eager for news of his many friends in England. We presently set out for the garden, through which M. Gentil very kindly conducted me. The concierge, from whom we obtained the keys of the glasshouses, is rather an interesting man. From the beginning of the war he secretly distributed anti-German literature, but was eventually discovered and imprisoned for ten months. He is very happy about it all now, and is particularly pleased to think that some information that they were able to get through to the British resulted in the destruction of a Zeppelin by a British aviator's bomb, which got a direct hit on the machine at its moorings. The garden has suffered a good deal during the war, mainly through the shortage of coal, necessitating the closing of some seven houses. As many plants as possible have been saved by crowding them into the remaining houses, but the overcrowding and the low temperature have been detrimental to their health. M. Gentil evidently did not intend to lose them all without a struggle, for he installed ordinary stoves in the houses with a view to using that method of keeping up the temperature if the supply of coal was insufficient to keep the furnaces going. So far he has not had to use them, and it is hoped that as soon as the transport problem is easier plenty of coal will be obtainable once more. The timber museum has also suffered, because the roof of the dome was unfortunately covered with copper. This the Germans removed, quite regardless of the fact that when it was gone the rain would drip through on to the exhibits. However, M. Gentil, in spite of his many trials, is extremely cheerful, and is looking forward to being able to replace his casualties and restore the survivors to their pre-war health. I expect to be demobilised during the next ten days, and if so I shall endeavour to accept the kind invitation of the hon. secretary to dine at the Horticultural Club on February 11."

The Ventilation of Potato Pits. — Serious losses have occurred this season in the pits of Potatos in various parts of the country. The Board of Agriculture advise growers to examine their pits at once. Where these are heated the owner should either turn, dress, and reclamp ware and seed separately or adopt a system of ventilation (1) by making ventilation holes about 1 foot square along the bottom and on both sides of the pit. At the same time the whole ridge of the pit should be uncovered. The bottom of the ventilation holes should be sloped so that rain runs away from, and not into the pit. Provision should be made for moisture to drain away by digging trenches around the clamp. During very severe weather these ventilation holes might be filled with loose straw; or (2) by removing the soil from the side of the pit, in strips, 1 foot wide, extending from the ridge to the base on both sides of the pit at distances of every 10 yards. The ridge of the pit should also be uncovered. During very severe weather these ventilation spaces should be filled with straw. By ventilating the pits in one or other of these ways it is hoped that the temperature will be kept normal, and that the gases developed in the pits will be replaced by fresh air

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Begonia Evansiana (see p. 40).—It is pleasant to read the praise of this handsome and old inhabitant of our greenhouses. It is, I believe, the hardiest member of its genus. I grew it out in the open here for many years, making the first start with some tubers imported direct from Japan. Afterwards, I planted out others from a greenhouse. The plants had no protection given them during winter, and reappeared in early summer for several seasons, but so late that they had insufficient time to reach their full growth before frosts cut them down. For a cool, shady place among Ferns, this Begonia might prove a very interesting plant if a little protection such as some coal ashes or Bracken were spread over the soil above its tubers each autumn. My plants died out through want of a little attention, and the clearing away of intruding neighbours, I fancy, rather than from winter cold. There is a very characteristic black-and-white portrait of a plant in that delightful book on the flora of Japan, *The Somoku-dzusetsu*, 20, *The Node Gardens, Welwyn.*

Damage by Snow at Aldenham Park.—One of the worst falls of snow in this district for many years past occurred on the evening of the 27th ult. Snow started to fall about 4.30 p.m., and though thawing at first, it later settled down heavily. Most of the snow was down before midnight, and the scene here the following morning was almost heartbreaking to an enthusiast, and nearly beggars description. We measured the depth of the fall at several places on the flat, and discovered that during the few short hours quite 9 inches had settled on the ground. The fine old Elms and Oaks in the park and specimen trees on the lawn suffered great damage. Even up to 11 a.m. huge branches could be heard crashing to earth, unable to support their white burden. Some had smashed through iron railings, others crumpled up wooden fences like so much paper, whilst others had fouled telephone wires, thus cutting "lines of communication"; in fact, all round the district telegraph poles and wires were brought down by the weight of frozen snow. Splendid Birches were torn asunder, whilst those which had resisted stoutly were twisted and contorted to destruction. Climbing Roses, Vines, and other climbers on poles were laid flat on the ground, as were clumps of bush Yews and various other bushy plants. It is strange that during my 34 years at Aldenham snow has never before wrought such havoc as it has done this winter and last. The snow has remained until to-day (Feb. 2), and even now the skies are heavy with threatened further falls. The work of salvage is grievously hindered, and many of the smaller plants on the ornamental clumps are still buried. The lesser members of shrub life, indeed, appear to have suffered even more grievously than large plants, and many specimen plants, the wood of which is brittle, have snapped off completely. I never remember seeing so much damage done in so short a time, and a realisation of how rapidly it all took place can be gleaned from an expression used by a neighbour, who described having heard throughout the night the rending and falling of branches in the park, and summed it up as being a "monotonous noise of great regularity, similar to the firing of a number of machine guns." Particularly serious was the damage done to the fine old Crataegus punctata, which was undoubtedly one of the finest specimens of this species in the world. I append a list of trees and shrubs which appear to have suffered most damage, as many of your readers will doubtlessly like to compare it with a list of their own sufferers. Those enumerated certainly do not appear to be good snow resisters on this occasion at Aldenham. Many of the plants are as yet still burdened, for, owing to the snow freezing hard on them, we can afford them very little relief. The value of good pruning stands out very distinctly in all cases, for unquestionably the trees and shrubs which met with the least damage were those which had been carefully tended in the matter of pruning and shaping. The havoc wrought by the snow was no doubt out of proportion to the actual depth of the fall, and I can only think that the reason for such disastrous happenings was that owing to the snow coming down in a semi-thawed condition, it packed very tightly wherever it settled, and its density was far greater than usual. As the half-thawed snow quickly froze, the branches of trees, etc., were actually burdened with several inches of semi-ice rather than snow. Preliminary list of most severely damaged trees, etc.:—Elms (a large number), Celtis, Alnus, Prunus (of sorts), Zelkovas, Robinias, Cydonias, Crataegus (in variety), Loniceras, Pittosporums, Oaks, Silver Birch (severe damage), Pyrus (of sorts), Acers (various sorts), Cornus (standards and bushes), Sophoras, Euonymus (of various varieties and forms), Cercis, Lilacs, Hippophaë (Sea Buckthorn). *Edwin Beckett, Aldenham House Gardens, Elstree, Hertfordshire.*

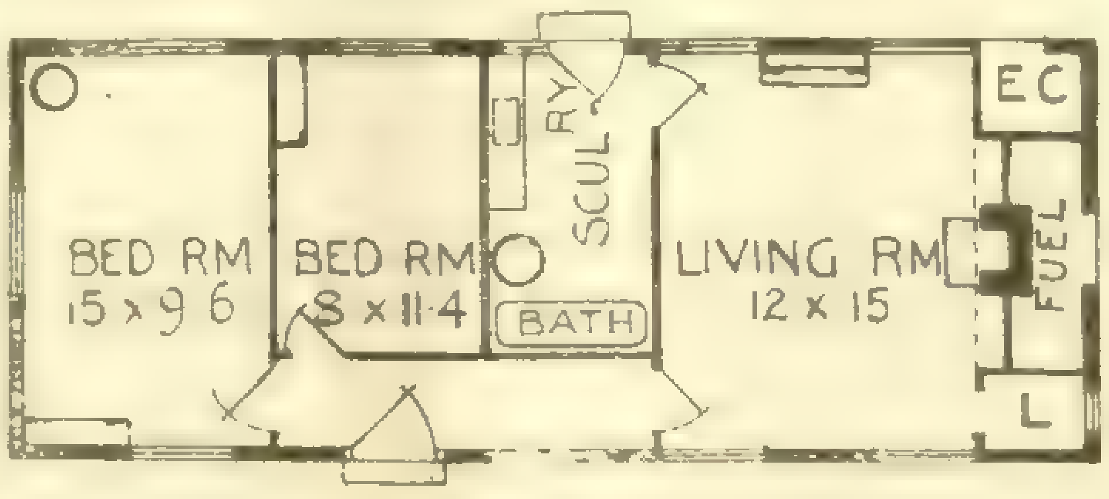
SOCIETIES.

ROYAL HORTICULTURAL.

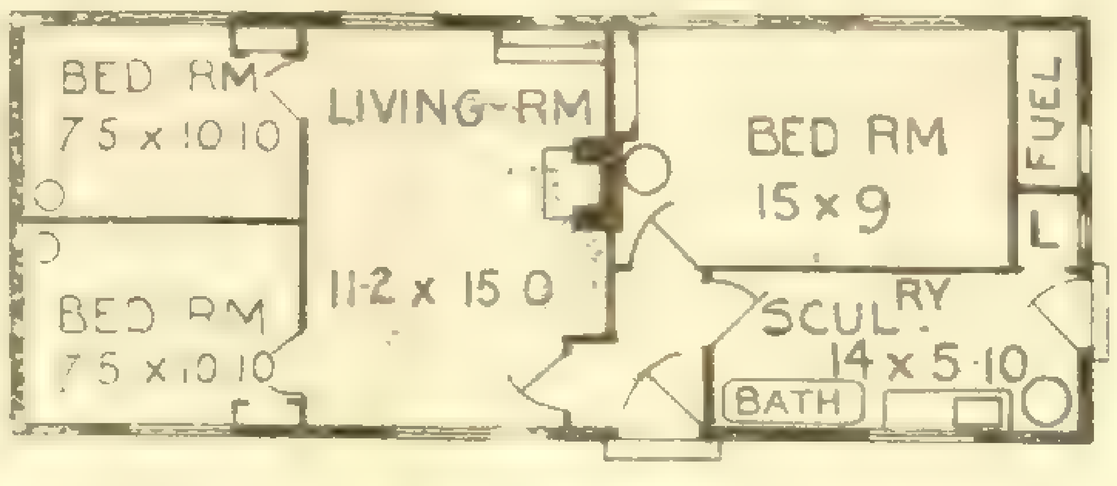
Scientific Committee.

JANUARY 28.—*Present:* Messrs. E. A. Bowles, M.A. (in the chair), F. J. Baker, C. H. Hooper, W. Hales, W. C. Worsdell, and F. J. Chittenden (hon. secretary).

Fruits from Salonika.—Mr. Worsdell reported that he had compared the fruits shown by Mr. Bowles at the last meeting with herbarium specimens, and had identified them as Marsdenia erecta and Periploca graeca.



TYPE A.



TYPE B.

FIG. 27.—PLANS OF COTTAGES MADE FROM ARMY STANDARD HUTTING: TYPE "A" HAS FOUR ROOMS AND TYPE "B" FIVE ROOMS.

(See p. 66.)

Flowers as aids to identification in Apple.—Mr. C. H. Hooper drew attention to a series of photographs of Apple stamens and styles made in Victoria, Australia, and published in the *Journal of the Dep. of Agr. for Victoria*, and remarked upon the great range of variation in arrangement and form exhibited. Unfortunately not all the flowers had been photographed at the same stage of development, but there can be no doubt that floral details may be a great aid in the identification of Apple varieties, and also in all probability to their classification.

Rogues in Beet.—Mr. Baker drew attention to the presence of long, fangy roots of a white colour in a crop of Beets grown from home saved seed of a particularly good stock of Globe Beets in an allotment garden. It had been suggested that the result was due to crossing with Spinach, but it seems more likely that crossing with either Mangolds or some other variety of Beet had occurred, for it is well known that crossing readily occurs among Beets unless they are separated by very long distances. It is, of course, possible that segregation in the F 2 generation was occurring.

Pritzel Committee.—Mr. Bowles announced that the Council were about to appoint an official representative of the Scientific Committee to act upon the Pritzel Committee, and the name of Dr. A. B. Rendle was suggested and unanimously approved. Dr. Rendle is now Professor of Botany to the Society.

Erythraea scilloides.—Mr. T. B. Rhys, of Tenby, wrote saying that he had discovered Erythraea scilloides growing wild in north Pembrokeshire. It had been identified at the British Museum and had never previously been recorded as wild in the British Isles.

BRITISH CARNATION.

OWING to illness Mr. W. E. Wallace, of Eaton Bray, Dunstable, was unable to open the conference arranged to follow a meeting of the General Committee of the British Carnation Society on Monday, the 27th ult., at the offices of the British Florists' Federation, 35, Wellington Street, Covent Garden. Great regret was expressed that illness should have prevented Mr. Wallace from attending, and the meeting agreed to send him a letter of sympathy. Mr. T. A. Weston signified his intention of resigning the secretaryship of the Society, as he proposed to take Charles Kingsley's advice and "Go West!" as soon as he is demobilised.

Instead of allowing the meeting to break up, members suggested a discussion, and Mr. C. Engelman was prevailed upon to open it. He succeeded uncommonly well, and raised such subjects as the classification of Perpetual Carnations, testing novelties by means of first-rate trials, the estimated reduction of Carnation cultivation since war commenced, and the reason why British-raised Carnations occupy such a low position in the flower markets as compared with American varieties. He suggested classification according to habit of growth; testing of novelties by some good grower for two or three years; estimated the reduction in cultivation to be 75 per cent. to 80 per cent., and considered British novelties were sent out before having been fully tested, consequently the market growers did not place much confidence in them.

A capital discussion followed, in which Messrs. W. H. Page, H. Mason, J. Page, junr., W. A. Sherwood, M. Allwood, G. Allwood, P. F. Bunyard, G. Cook, C. H. Curtis, Thos. Stevenson, and Mr. J. S. Brunton (chairman) took part, and, finally, the questions of classification and trials were referred to the Floral Committee for consideration and report.

We may add that the British Carnation Society proposes to hold a dinner and conversazione during the evening of the second day of the R.H.S. Chelsea show.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 3.—As a consequence of the strike among workers on London's tube railways there was a very small attendance at the annual general meeting of the National Chrysanthemum Society, held at Essex Hall, Strand, on Monday evening last. In the absence of the President, Sir Albert Rollit, Mr. Thomas Bevan presided. The business was despatched with promptitude. After the usual preliminary items were passed, the report and accounts as circulated among members were taken as read, and on the motion of Mr. Bevan and Mr. Hawes they were adopted unanimously. The following are a few extracts:—

Notwithstanding the fact that severe war-time conditions prevailed throughout the greater part of the year, the committee has the pleasure of submitting a record of good work accomplished, a successful show held, a satisfactory financial position, and a reserve fund of £— still intact. At the end of 1915 the outlook for floricultural societies was anything but bright, and the shadows deepened as war, with its inevitable distress and financial strain, continued. However, in spite of all difficulties, the National Chrysanthemum Society carried on its work so far as circumstances permitted, and has come through the troublous period of the Great War with an unbroken record, and a position that will allow the revival of its former activities as speedily as trade and amateur growers are able to take up more fully the peaceful art of flower production. It is worthy of record that the Armistice was signed on November 11, a date when Chrysanthemums were the most prominent flower in gardens, markets, and florists' shops. Without the grace and brightness imparted by the Society's name flower the festivities which followed the cessation of hostilities, and the Christmas gatherings of 1918, would have lacked that gaiety, attractiveness, and suggestion of Peace which flowers alone are able to impart.

The work of the Floral Committee was limited, as many raisers felt it was hardly worth their while to submit novelties at a time when there was little prospect of a brisk demand for them. This committee met on five occasions, discussed the merits of seventeen varieties submitted, and granted one First-class Certificate and five Commendations.

At the conclusion of hostilities the committee appointed a sub-committee to draw up select lists of Early-flowering Chrysanthemums. Owing to the length of the trade lists available, and the difficulty of reducing the synonyms, the work is not yet complete, but the committee hopes the lists will be ready for publication before planting time arrives.

At the annual general meeting, held in February, 1918, the presentation to Mr. Richard A. Witty was made by Mr. Thos. Bevan, in the unavoidable absence of the president. Mr. R. A. Witty was compelled to resign the secretaryship of the society at the end of 1917, owing to pressure of business, and the presentation to him of a handsome drawing-room clock and an illuminated and framed address was a tangible recognition of the services he had so ably rendered the society during 11½ years' service.

In the near future the society should find an opportunity to resume and extend its former activities. Already the committee has under consideration the question of frequent general meetings for the discussion of matters relating to the Chrysanthemum, lectures to affiliated societies, and an extension of the show schedule. But to enable the committee to carry out a progressive and educational programme an increased income will be necessary.

The accounts show a turnover of £169, a balance of £17 0s. 7d. carried forward, a surplus over liabilities of assets amounting to £108 14s. 10d., and a reserve fund of £75.

All the officers and members of committee were heartily thanked for past services, and Mr. S. J. Bayley was appointed co-auditor with Mr. R. A. Witty, in the place of Mr. Walker, retired. The officers were all re-elected for the ensuing year, i.e., President, Sir Albert Rollit; Treasurer, Mr. John Green; Chairman of Committee, Mr. Thos. Bevan; Vice-Chairman, Mr. E. F. Hawes; Foreign Corresponding Secretary, Mr. C. Harman Payne; General Secretary, Mr. Charles H. Curtis. The twelve members of Committee retiring by rotation were all re-elected, and Mr. Thos. Stevenson, Mr. M. Sargent, and Mr. B. Carpenter were elected to fill vacancies among those who retire in 1920 and 1921.

Some of the members suggested the revival of the Society's annual dinner and summer outing, and the holding of a smoking concert by way of a reunion for metropolitan members.

A vote of thanks was accorded Mr. Bevan for presiding.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 16.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. Cypher, J. Evans, J. Howes, A. Keeling, D. McLeod, J. McNab, W. Pickup, E. Rogers, W. Shackleton, and H. Arthur (Secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Lycaste Skinneri alba magnifica, Spathoglottis Petre and *Catasetum splendens Lindenii*, from Mrs. BRUCE and Miss WRIGLEY.

Cypripedium Conference (Chardwar Bulldog × Hera-manii), from S. GRATRIX, Esq.

Odontoglossum crispum Virginale Leeanum var. Pickupiae, from W. PICKUP, Esq.

Odontoglossum crispum var. Wilps, a heavily blotched variety, from P. SMITH, Esq.

Cypripedium The Major (Gaston Bulteel × Harrisianum superbum), from T. WORSLEY, Esq.

AWARDS OF MERIT.

Cypripedium Draco, Bridge Hall var., from Mrs. BRUCE and Miss WRIGLEY.

Lycaste Redwing (supposed natural hybrid), from S. GRATRIX, Esq.

Cypripedium Odin (Sunrise × Antinous), from W. R. LEE, Esq.

Cypripedium Lebal (Leeanum Clinkaberryanum × Hannibal), from T. WORSLEY, Esq.

AWARD OF APPRECIATION—1ST CLASS.

Odontoglossum Gorizia (President Poincaré × Jasper), from W. R. LEE, Esq.

A Silver-gilt Medal was awarded to Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. Rogers), for a group of Cypripediums, and S. GRATRIX, Esq., Whalley Range (gr. Mr. J. Howes), was also awarded a Silver-gilt Medal for a group of Cypripediums and Odontoglossums. WM. PICKUP, Esq., Great Harwood (gr. Mr. H. Mercer); T. WORSLEY, Esq., Haslingden (gr. Mr. T. Wood); W. R. LEE, Esq., Heywood (gr. Mr. C. Branch); P. SMITH, Esq., Ashton-on-Mersey (gr. Mr. E. W. Thompson); Messrs. KEELING AND SONS, and Mr. W. SHACKLETON (Bradford), also staged exhibits, and Messrs. CYPHER AND SONS, Cheltenham, staged a group of various Orchids for which a Silver Medal was awarded.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL.

JANUARY 29.—At the meeting of the above Society, held on the 29th ult., a paper entitled "A Talk About Potatos" was read by Mr. Robert L. Scarlett, Sweethope, Inveresk, Midlothian. Mr. John Cairns, of Messrs. Austin and McAslan, presided.

The lecturer dealt with his subject in relation to the recent history of Potatos, which is changing rapidly, owing to the prevalence of Wart Disease. The introduction of many new coloured varieties was foreshadowed since allotment holders have seen fit to grow them more extensively. Spraying as a preventive of blight was strongly advocated, more especially when it is borne in mind that many varieties of the best quality are more or less susceptible to disease. In breeding new varieties there has to be kept in the forefront immunity to Wart Disease, and good quality. These are the chief assets in the public's estimation. Emphasis was laid on the recent work of the Scottish Board of Agriculture in their efforts to promote a National Plant Breeding Station to develop new varieties, and the inauguration of organised registration of new Potatos with a view to the elimination of too-much-alike varieties, while the efforts of the Board to control Wart Disease were discussed and strongly supported.

BARNET NATURAL HISTORY.

JANUARY 14.—At the meeting of the above society, held on the 14th ult., Mr. A. Wilson, Hadley Bourne Gardens, Barnet, gave a lecture entitled "Some Insect Pests," illustrated by lantern slides. The lecturer pointed out that wireworms, which are the larvae of the Click Beetle, or Skip Jack, exist in that stage from three to five years, and were the most persistent and destructive of all ground vermin. Soot, lime, salt, nitrate of soda, and superphosphate were manures that were directly destructive to them, and they might be trapped by burying pieces of Potato, or Carrot, or thick slices of Beetroot in the ground and examining them from time to time. Centipedes were carnivorous, but millepedes fed chiefly on soft vegetable matter, and the common snake millepede, and another, not quite so long, the lecturer considered to be the greatest enemies of growing Potatos. Leather Jackets, the larvae of the Daddy Longlegs, could be dealt with in the same manner as wireworms. Mr. Wilson also dealt with the Onion Fly, the Carrot Fly, the Celery and Parsnip Fly, the Black Currant Gall Mite, the Shoot and Fruit Moth of the Red, White, and Black Currant, the Cabbage Butterfly, the Vapourer Moth, and many others, and the best means of destroying them. In replying to a question, the lecturer expressed the opinion that the large increase of caterpillars in the summer of 1917 was due to the number of insect-eating birds which had died during preceding hard winters.

DEVON AND EXETER HORTICULTURAL.

JANUARY 24.—A special general meeting of the Devon and Exeter Horticultural Society was held at the Guildhall, Exeter, on the foregoing date. Mr. P. C. M. Veitch presided.

The hon. secretary, Mr. T. A. Andrews, reported that at the commencement of 1916 the Society had a balance in hand of £46 6s. 9d. Owing to the continuance of the war and the adverse conditions the exhibition proposed to be held in the autumn of that year was abandoned. During 1916, 1917, and 1918, only a very limited number of subscriptions was received, and therefore it was financially impossible to hold a show in either of those years. Owing to the generosity of subscribers the balance was now £88 18s. Under these conditions the Committee recommended that an exhibition be held next autumn.

It was decided by the meeting to hold the show at the end of October.

Mr. E. Plummer was elected President, and the Vice-Presidents were reappointed, with the addition of the incoming High Sheriff of the County (Mr. W. P. Martin), the Mayor of Exeter (Sir James Owen), and the Sheriff of Exeter (Mr. W. Townsend).

WINCHESTER GARDENERS'.

ON the 28th ult. the Rev. A. G. Bather presided at the annual meeting of the Winchester and District Gardeners' Association, held at the Oddfellows' Hall, Winchester.

There was a large attendance of members to receive the Report and Accounts for 1918. The former recorded the holding of six general meetings, participation in the Hospital Fête, several instructive lectures, and a fair membership. The accounts showed a balance in hand of £18 16s. 10½d. The president, who gave an interesting address, was re-elected, as were Mr. Wise, chairman; Mr. Taylor, treasurer; and Mr. H. J. Boorer, hon. sec. Mr. Watts staged a capital exhibit of Potatos and a collection of Wallflowers.

CROPS AND STOCK ON THE HOME FARM.

PREPARATIONS FOR SOWING OATS.

UNDER favourable conditions February is the best month in which to sow Oats in the South of England. When Oats are sown early in well-tilled soil the plants escape many of the troubles which beset those sown later. When sown in April a firm, deep root-hold is not obtained before dry weather sets in, and the crop is severely handicapped. Early-sown Oats are ready to harvest early, and ripen more uniformly than those sown later. These late sowings germinate unevenly and grow irregularly, and the straw is liable to ferment in the rick, thus reducing its feeding value for cattle.

Another point in favour of early sowing is that much less work—ploughing, harrowing and rolling—is required. For Oats sown on a "stale fallow"—autumn or winter plough—the ground does not, as a rule, require more than three, or at the most four, harrowings after sowing, and hardly ever ploughing or rolling, because the soil will have been thoroughly pulverised by frost, rain and wind.

Now is the time to determine whether a certain field will require ploughing before sowing. For example, Oats are to follow a last season's Wheat crop, the stubble of which was ploughed during November or December. If the field promises to be weedy by the middle or end of February it should be ploughed at once, to provide a clean surface. I need hardly say that ploughing should not be done during wet weather, especially if the soil is retentive. Stubble or other land carrying surface weeds should be carefully ploughed, using the skim coulters adjusted to ensure the burial of weeds.

The best variety of Oat to sow will depend upon local circumstances. If Oats are grown for home use, i.e., for horses, cows, pigs, poultry and sheep, and the straw for bedding and feeding, it is difficult to name a better variety than the Black Tartarian, as this gives a heavy yield of corn and good straw. From 48 bushels to 60 bushels of corn per acre is a reasonable yield, and 30 cwt. to 2 tons of straw per acre is not an uncommon return. Where Oats are grown for sale as well as for feeding, then local requirements should be taken into consideration. In some counties White Oats are popular, but black ones are usually preferred. Of white varieties, White Hero, Victory, and Abundance are desirable: the first is of sturdy growth and yields well. Of black Oats I know none superior to Black Tartarian as an all-round variety. I am a firm believer in sowing good seed. Oats weighing from 38 lbs. to 40 lbs. per bushel, after being well screened to take out weeds and small corn, I regard as good seed. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

FAIR WAGES.

CASES have been brought to the notice of the Agricultural Wages Board in which yearly hiring contracts have been made which provide for

payment of agricultural workers at less than the minimum rates of wages fixed by the Wages Board for the district. Such contracts, like all agreements for payment or acceptance of less than the minimum rates, are void under the provisions of the Corn Production Act, and the payment of any worker at less than the minimum rate applicable to him under the Act would render an employer liable to prosecution notwithstanding any hiring contract or other wage agreement to the contrary.

FOOD FOR PHEASANTS.

As the Food Controller has revoked the Feeding of Game Order, 1917, the Board of Agriculture has revoked the Pheasants (Rearing) Order, 1917, which prohibited, except under licence, the hatching and rearing of pheasants by any artificial means.

TRADE NOTES.

DISSATISFACTION in the horticultural trade with regard to the competition of co-operative societies continues to spread. Meetings are being convened by a certain co-operative society in all parts of the country, at which the opportunity is taken to advertise a trading concern with which it is intimately connected, and to urge customers to buy from the latter rather than from the recognised firms who have devoted so many years to training a skilled staff for the purpose of producing reliable stock. These meetings are frequently attended by Government officials, who speak in support of the society.

IT would not be surprising if the Chancellor of the Exchequer, in his search for further sources of revenue, were to make careful inquiry into the development of co-operative societies in general, and the immunity from income tax which they at present enjoy. Societies of this nature were originally regarded as being somewhat in the light of friendly societies, but in recent years many of them have developed into commercial concerns, seeking by every means in their power to attract business away from the ordinary trader. Every firm and company has to pay income tax on its profits with the exception of co-operative societies, and it is difficult to see why the latter should not contribute in equal proportion. The loss of revenue in this direction can be estimated by the fact that one well-known co-operative society, together with those affiliated to it, can boast a turnover of over £6,000,000 per annum.

IT is a favourite argument against the liability of co-operative societies to pay income tax that, although they are not called upon to pay on their profits, their members are nevertheless liable to include in their individual returns for income tax purposes the value of any benefits which they may receive as members of such society. In practice, of course, the matter does not work out in any such way. There must be comparatively few cases in which those members who make any income tax returns remember to schedule the benefits received as part of their assessable income, but the question goes far beyond this. Since the Industrial and Provident Societies Act was passed, the minimum income in respect of which income tax is payable has been considerably reduced, and in order to facilitate collection many employers deduct, as agents for the Government, income tax from the wages of their workpeople. No enquiry is made of the workman as to whether any additional income tax is chargeable against him on account of his membership of a co-operative society, and in consequence the whole of this source of revenue at present appears to be lost to the Exchequer.

IT is certainly anomalous that even the smallest trading company registered under the Companies Acts is liable to pay income tax on its profits, while a commercial concern registered under the Industrial and Provident Societies Act goes free.

THE scheme for a League of Trade Associations, representing horticulture in all its branches, appears to be now assured of success. The best evidence that the Chamber of Horticulture is determined to hold the balance evenly between the various sections of the trade may perhaps be found in the fact that hitherto the chief criticisms in the fruit trade have been mutually destructive; that is to say, some growers' associations have suggested that the salesmen's section may become too largely represented, while on the other hand at least one salesmen's association has hesitated to apply for membership for fear lest the growers' element should become so powerful as to over-ride the former's interests. These matters have, however, now been adjusted, apparently to the satisfaction of both parties.

A MUCH more difficult question will probably arise for the decision of the Chamber of Horticulture in connection with the desirability or otherwise of a policy of free imports. Home growers naturally wish for some machinery to prevent the market being glutted with supplies from outside sources during such time as there may be a sufficient supply of home produce. On the other hand, agents in England for foreign growers, with equally natural enthusiasm, support a policy of free imports without restriction during any period of the year. A debate on the subject convened by the Chamber of Horticulture would furnish an interesting topic, but it remains to be seen whether the Chamber will decide to give any lead in either direction, or whether the executive will decide that, in default of reasonable unanimity on the point, they should leave the matter to be dealt with by the various trade associations. Certainly there are enough reforms overdue for the benefit of horticulture, in respect of which there is no disagreement in the trade, sufficient to occupy the energies of the Chamber for some time to come, and under the remarkably able leadership which the Chairman, Mr. George Monro, junr., has already shown, it is safe to assume that members will not be kept short of food for reflection in various directions.

Now that so many soldiers are being demobilised it is very desirable that certain doubtful points as to the extent to which their terms of employment (in the absence of express agreement to the contrary) are affected by ancient custom should be placed beyond the possibility of dispute. It is hoped to publish in an early issue an article dealing with this subject, particularly as regards the length of notice to be given when either employer or workman wishes to terminate the engagement. The position of a head gardener has already been decided in a well-known case, but the position of under gardeners appears to be open to considerable doubt.

THE concession which the Japanese Bulb Control Committee has secured from the Board of Trade will probably not be utilised to the full by Japanese growers this season. However, steps are already being taken by the Committee with regard to next season's imports, and it is hoped that by that time larger supplies may be available.

THE Horticultural Trades Association of the United Kingdom is taking a vote of its members as to the advisability of registration under the Companies Acts as a company not for profit, limited by guarantee. It is proposed to apply to the Board of Trade for leave to omit the word "Limited." Now that the Association is enlarging its organisation the suggestion should prove convenient in several respects, and other associations may be expected to follow suit.

Obituary.

C. G. van Tubergen.—It is with deep regret we have received intimation of the death of Mr. C. G. van Tubergen, which took place on January 25, at Haarlem. The deceased gentleman was well known among lovers of hardy plants and rare bulbs as head of the firm to which he gave his name, a firm comprising the brothers Hoog and Tubergen. Mr. C. G. van Tubergen was 74 years old, and his remains were laid to rest on January 28 at the Shoterweg Cemetery.

Answers to Correspondents

DAMAGED RHODODENDRON LEAVES: *G. F.* The Rhododendron leaves have suffered, as you suggest, from the application of an excessively strong insecticide, and nothing will bring them back to their original form and colour. Very careful treatment will be necessary to prevent the leaves from falling. An excess of water at the roots must be guarded against, and new growth should be encouraged by frequent light syringings in fine weather and by top-dressing the roots with leaf-soil and peat.

FAILURE WITH RICHARDIAS: *Calla.* From the small amount of evidence received it is difficult to judge accurately the cause of failure, but as the few remaining surface roots are healthy, and all the lower ones dead, over watering seems to be the cause. All plants with tuberous or bulbous roots require very little water for some time after they are potted, provided the soil used to pot them in is fairly moist.

LAWNS: *I. O.* A useful little book giving the particulars you require is *Lawns and Greens*, by F. W. Sanders; this can be obtained from our publishing department, price 1s. 9d., post free.

NAMES OF FRUITS: *G. A.* The specimens were badly shrivelled, and therefore not in a good condition for naming; they probably represent Bramley's Seedling.

NAMES OF PLANTS: *C. A. W.* 1, Buddleia variabilis; 2, Skimmia japonica; 3, Colletia spinosa; 4, Acacia armata; 5, Cupressus (Retinispora) pisifera plumosa; 6, Juniperus communis nana.—*Hythe.* 1, Iris japonica (syn. chinensis); 2, Epidendrum radicans.—*F. G. A.* 1, a species of Cotoneaster; 2, Olearia Haastii; 3, Euonymus japonicus aureus; 4, Cytisus fragrans; 5, an Oncidium (send when in flower); 6, not recognised—the specimens were miserable scraps and altogether unsuitable for the purpose of identification.

SLUGS ATTACKING POTATOS: *T. B. A.* Superphosphate acts as a deterrent to slugs, and is an excellent fertiliser to use for the Potato crop. Dust the fertiliser along the rows when they are opened for planting the sets, at the rate of 2 or 3 ozs. to the square yard. A little sulphate of ammonia applied either when the rows are filled with the soil or just previous to the haulm appearing above the ground will also be of value.

TRAINING IN HORTICULTURE: *Miss C. D. W.* Insert an advertisement in one of the gardening papers, offering your services, as you suggest, in return for training, board, and lodgings.

THE PAJARITO FLOWER: *H. E.* There are several Chilian plants known by the name of Pajarito, but obviously the plant described in your letter under this name is Pasithea coerulea D. Don., syn. Anthericum coeruleum Ruiz and Pav.

WAGES BOARD: *B. C.* We can give you no further advice beyond that contained in the official note published on p. 43. You will notice that the Wages Board expressly stated that they cannot give legally binding decisions in such cases as yours, but that gardeners employed in private or estate gardens, the produce of which is grown wholly or partly for sale, would, in the Board's view, come within the scope of the minimum rates.

MARKETS.

COVENT GARDEN, February 5.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

Heather, white, per doz. bun....	6 0–10 0	Violets, single, per doz. bun. ...	6 0 10 0

REMARKS.—The supplies of most home-grown flowers have been lessened by the severe weather during the past week. Arums (Richardias) and Lilium longiflorum are greatly reduced in number, and the prices have risen accordingly. Daffodils appear to be sufficient for the demand, although prices are higher. Pheasant-Eye Narcissus increases in quantity as well as quality, and prices are becoming normal. The supplies from Guernsey and Scilly have been reduced during the past week, as also those from the West of England. The arrivals of French flowers have been very erratic. Paper-White Narcissi begin to show signs of finishing, and the best flowers have practically doubled in price. A few Violets are now arriving in good condition and selling freely at high prices. There is abundant supply of Acacia, and Anemone and Ranunculus are arriving more freely.

MANCHESTER SEED HOUSE.

DICKSON & ROBINSON'S Establishments
Cathedral Street—in the City.
Head and General Offices.
Farm and Garden Seed Warehouses:
17, 19, and 21, Robert Street,
Cheetham, Manchester.

DICKSON & ROBINSON'S Vegetables. Hercules Pea, 2s. 6d. pint; Premier Onion, 1s. 6d. and 2s. 6d. pkt.; Giant Exhibition Runner Bean, 2s. 6d. pint; Prolific Long-pod Broad Bean, 3s. 6d. quart; Aviator and Moneymaker Tomatos, 6d. and 1s. pkt.; and others in Cauliflower, Cabbage, Broccoli, Brussels Sprouts, Beet, Savoy, Cucumber, Celery, Leek, Lettuce, Parsnip, Vegetable Marrow, &c.

DICKSON & ROBINSON'S other Onion—ROYAL KEEPER.—Another fine variety, with remarkable keeping and cropping qualities. Flesh mild and firm. Skin of a deep brown colour. In shape it comes between the globe and flat sections. A distinct variety, 1s. 6d. and 2s. 6d. pkt.

ROYAL KEEPER—a Head Gardener's opinion:—I have a very high opinion of your "Royal Keeper." I have grown it for three years on the same ground with other varieties, and it has always been immune from all diseases which attack the Onion. Other varieties have been ruined with attacks of mildew and fungus growth. Through its healthy and robust constitution it has resisted all diseases. I think it the finest Onion in cultivation. For its late keeping qualities it has no equal.

DICKSON & ROBINSON'S Catalogue, complete and descriptive of all the best in vegetables and flowers, is free for the asking, and request puts enquirer under no obligation.

THE SELECTION AND PROPAGATION OF PARADISE STOCKS.

THE completion of the first stage in our work amongst fruit-tree stocks, marked by the sorting out of the varieties into their true types, and the establishment of true stool beds, has come at a very opportune moment in many ways.

During the years of war, the fruit-tree trade has been very uncertain, and planting in a large measure restricted. The importation of stocks from abroad has ceased, and, owing to the shortage of labour, the stock beds of many nurserymen, who were accustomed to raise their own Apple and Quince stocks, have received scant attention.

The signing of the armistice, the talk of extensive land settlement, the high prices of English Apples, and the prospect of the removal of restrictions, have all tended to create a boom in the fruit-tree world, and there is a general call for stocks.

If the researches at East Malling on this question are to be of real value to the present generation of fruit growers and fruit-tree nurserymen, now is the time.

SUMMARY OF CLASSIFICATION.

The Report from the Experiment Station at East Malling in 1917 on "Paradise Apple Stocks" (*Journal R.H.S.*, Vol. XLII.), amply proved the existence of a wide range of root systems of very different vigour and desirability, all masquerading under the name of "Paradise." Whilst at one end of the scale there were found root systems approaching what is generally described as "free" or "crab" rooting in character, at the other end there were types so lacking in coarse roots and so surface rooting that without further experiment they could safely be pronounced as very dwarfing in tendency.

After lifting many hundreds of stocks of the various types, it is possible to say that there is a remarkable uniformity of root system in each group

Moreover, the characters portrayed in the roots have been very generally confirmed in the vigorous or stunted appearance of wood growth, so that it has become to some extent safe to predict what are likely to be desirable or undesirable root systems for special purposes.

The logical conclusion at which these experiments are aiming is to test these series of root systems, worked with strong, medium, and weak-growing varieties, and to plant them in heavy, medium, and light soils. Batches of trees are now actually worked for this purpose, but it must necessarily be a matter of some years before we can draw any more very definite conclusions.

Nevertheless, we are faced at this moment with the dearth of stocks in this country, with the opportunity of establishing fresh and true stock-beds very widely, and thus of very rapidly improving the general level of trees both from the fruit-grower's and the nurseryman's point of view. Therefore, those laying down new stool beds, who have decided in future to raise the bulk of the stock they require themselves, look to East Malling for some indication of the most promising types to propagate as quickly as possible. Growers also want to know on what variety of stock to ask for worked trees.

PRACTICAL RESULTS ALREADY OBTAINED.

In October, 1918, a representative Conference of Nurserymen, under the auspices of the Horticultural Trades' Association, met at the Fruit Experiment Station, East Malling, and discussed these matters at some length.

The Conference marked a distinct step forward in ideas about fruit-tree production. Nurserymen were only too ready to acknowledge the diversity and confusion amongst the stocks often in common use, and they were equally agreed as to the desirability of having uniformity within a specified type. First, it was decided that the classification made at the Fruit Station should be accepted by the trade, and that a recognised and uniform naming should be adopted as follows:—

Type 1.—Broad-leaved English Paradise.
Type 2.—Doucin (commonly "English Paradise").
Type 5.—Improved Doucin (Amélioré).
Type 6.—Nonsuch Paradise.
Type 8.—French Paradise.
Type 9.—Jaune de Metz Paradise.

The other types, the identity of which appears as yet to be uncertain, were still to be known by their numerals. Type 7 appears rather a desirable stock of this class.

In the second place, nurserymen immediately put in hand the question of having their stock-beds "rogued" and named according to type.

At the present time the Fruit Experiment Station has supplied some 26 nurserymen with a limited number of stocks of various types for stool bed-making, and we have already started the "roguing" of existing stock-beds. Therefore, within a very short time, fruit growers may look forward to buying their bush Apples upon guaranteed stocks of definite type.

They will be wise to recognise this real advance by ceasing to clamour for "cheap" trees, and be anxious to buy only the best. Cheap trees are never cheap to the commercial fruit grower. To encourage the trade in this advance in practice, growers must be prepared to pay slightly above normal prices for guaranteed trees.

RELATIVE MERITS OF VARIOUS STOCKS.

The only moot question at the present stage in the researches is which stock is most desirable. About this nurserymen were not entirely in agreement. That Type 1, the Broad-leaved English Paradise, has the name and reputation everyone was willing to admit, but our investigations long since revealed that it was far less commonly used than is supposed, though the name was frequently used for other varieties. From general observations, it appears a desirable stock for several reasons.

It is easily raised from layers and cuttings. It grows sturdily and healthily and is little feathered. As it matures it has a well balanced root system between coarse lateral roots and branched fibre.

Of the Paradise Stocks it is probably one of the most vigorous, and should be highly suitable for permanent bush trees and possibly even for half-standard trees.

It is an easily recognised stock.* It does not appear to be raised abroad at all, but it shows every sign of being both a nurseryman's and a fruit-grower's stock.

Type 2, the Doucin, commonly known as "English Paradise," is by far the most widely used stock both in this country and abroad, which fact should testify to its desirability. On our soil it is less easy than Type 1 to root from layers, and very uncertain from cuttings. It grows sturdily and healthily, but is distinctly coarser and more feathered than the Broad-leaved Paradise. As it matures, it appears to develop little branched fibre from its coarse lateral roots. In all probability it produces a bush tree of moderate size. One would suppose it to be slightly more dwarfing than the Broad-leaved. By some of the older writers it is commended as a stock for heavy soils.

Perhaps the main disadvantage to the wide use of this stock in the past has been the fact that it has been so largely imported from abroad, whence it frequently arrives mixed with two very undesirable types of Paradise, Types 3 and 8 (the French Paradise). Standardisation and home-raising should counteract this disadvantage.

Type 5, the improved Doucin, would appear to be a stock altogether more dwarfing in habit, and possibly more suitable than Types 1 and 2 for cordon trees, espaliers, and other forms of trained trees used in gardens.

* The method of identifying the various stocks is fully described in the copiously illustrated report in the *R.H.S. Journal* already referred to.

It roots very readily from layers or cuttings. It is moderate in vigour, healthy, and with a clean stem for working. It does not develop a very spreading root system, but forms a considerable amount of fibre around the collar.

That this might make a very good stock where a dwarfing characteristic is especially desired seems likely. It very often comes from abroad mixed with undesirable types.

Type 6, the Nonsuch Paradise, is, in fact, in far more common circulation than the Broad-leaved Paradise at the present time. Opinion as to its virtues are, however, far more varied. It is said to encourage very early cropping. On our ground it is raised very easily, from layers or cuttings. It grows somewhat coarse and sappy, and often continues in growth late in the season, retaining its leaves until Christmas or even later. It appears generally healthy, and as it matures it develops a vigorous root and branch system. It is difficult without further data to compare its merits with those of the Broad-leaved, though it does not produce a stock for working of nearly such good quality.

If another stock of distinctly more dwarfing tendency is required, either Type 9, Metz Paradise, or Type 4 (M. pumila) may be chosen: both appear healthy, dwarfing, and are fairly easily raised. Whilst the former is somewhat late in coming into leaf, the latter is very early.

At the other end of the series is a group of types numbered from 10 to 16, some of German and some of English origin, which appear far more vigorous even than Broad-leaved English Paradise. They are easy to raise from layers, and probably from cuttings, and yet they develop a root and branch system which appears to possess the necessary qualities for a selected "free" stock for standard work. Types 13 and 16 seem especially promising in this respect. Thus it is hoped also to standardise "free" stocks along similar lines. *Ronald G. Hatton, Director, South-Eastern Agricultural College, Wye, Kent.*

(*To be concluded.*)

NOTES ON IRISES.

AN EARLY-FLOWERING IRIS.

Iris Bakeriana is a delicate little species from the hills in Northern Mesopotamia, and though it lived and flowered here for some years with a glass roof over its head, I am afraid it has now succumbed to lack of attention during the war. It is, therefore, some consolation to find that the original of the accompanying sketch (see fig 28), of which Max Leichtlin sent me a single bulb some ten or twelve years ago, is able to hold its own in the open, and thus to atone to some extent for the loss of one of its parents. For, although it usually goes by the name of I. Bakeriana melaina, it is really a hybrid between I. Bakeriana and I. reticulata. This, I think, I have proved by making the cross and obtaining a range of forms, of which one or two were practically identical with Leichtlin's plant. The foliage of the hybrids is interesting, for, while the leaves of I. Bakeriana are cylindrical, with eight projecting ribs, and those of I. reticulata are four-sided, those of the hybrids have six ribs.

Leichtlin's name of melaina, or black, is very appropriate, for the tips of the falls are of the most intense, velvety, dark reddish-black-purple. The central portion is white with a number of irregular linear blotches of the same colour. It is interesting to note that, although all the members of my present little colony of bulbs have sprung as offsets from one original bulb, yet the markings are never exactly similar on any two flowers. Differences, at any rate in colour, can therefore arise in individuals that have originated in vegetative, as opposed to sexual, methods of increase. *W. R. Dykes, Charterhouse, Godalming.*

THE MARKET FRUIT GARDEN.

Work was quite as much interrupted by bad weather in January as it was in the preceding month. There were only nine days without either rain or snow, the total fall at my place being 5.28 inches, which is much above the average. At no time was the land in a fit state for planting fruit trees, and the women diggers have not been able to dig the ground for six weeks. Thus there are serious arrears of winter work to be overtaken, and it is to be hoped that February will give ample opportunities for this to be accomplished. Fortunately it has been possible to make fair progress with pruning, although this has been done under very depressing conditions. It was not until the end of the month that wintry weather set in in my district, which escaped the

Fig. 28.—Iris Bakeriana melaina (I. Bakeriana × I. reticulata.)

heavy falls of snow reported earlier from many localities. The first snow fell on the 27th, but did not lie. It was not until the 30th that there was anything like a heavy fall, and it is still coming down as I write. The snow is not particularly welcome, but the lower temperature that accompanies it is desirable as a set-back to too-forward vegetation. Primroses have been blooming in the hedgerows for some time. Crocuses are just showing yellow in the garden, and some of the female blooms have appeared on Cobnut trees. The lowest temperature recorded during the month was 11° of frost 4 feet from the ground on the night of the 30th.

Fruit Prospects.

After the rest which most fruit trees had during 1918, they may fairly be expected to crop well during the coming season. The present appearance of Apple, Pear, Plum, and Cobnut trees bears out this hope, for they are, generally speaking, well supplied with fruit buds. Plenty of bloom may therefore be predicted with certainty, but the fate of the crop will, of course, be decided by the weather at blooming time. Needless to say, a full yield is greatly desired this year, not only by growers, but also by the public and the jam makers. No one wants prices to be so high as in 1918, but they are sure to be good, however big the home crop, because imports cannot be expected to reach anything like pre-war dimensions for some time to come. One reason why a heavy crop is very desirable is that it might steady public opinion with regard to fruit-growing. As a result of last year's short harvest, restricted imports, and consequent abnormal prices, fruit-culture is being boomed to an extent that is not justified by prospects. People are planting largely, and both the Government and the jam manufacturers have schemes for encouraging still more planting. It is difficult to understand what excuse there is for this. By the time these newly-planted orchards are in bearing it is more than probable that overseas supplies will be normal, and we shall return to the old conditions of full markets and low prices. The fruit scarcity and high prices of one quite abnormal season have caused some people to forget the many years in which fruit has been almost given away in the wholesale market.

Ploughing in Orchards.

Digging under fruit trees in winter has always been something of a nightmare to fruit-growers, partly because the work is so often interrupted by the weather, but still more because of its expense. During the war, with labour scarce and wages high, some growers have found it impossible to get all their digging done, and orchards have been allowed to fall down to grass. Fortunately the situation has stimulated invention, and it is now possible to cultivate quickly and cheaply with a special plough in a great many orchards. I have thoroughly tested the new Fruit Farm Plough introduced by Messrs. Seabrook and Udall, and am very well satisfied with the result. Wherever the spacing of the trees allows of its use this implement effects a big saving of time and expense as compared with digging, and weeds are covered much more thoroughly than by digging with forks, as is usually done. The special feature of the plough is a simple adjustment of head and handles which enables them to be set at an angle to the beam. This allows the horse or horses and man to walk outside the spread of the branches whilst ploughing right under the trees. The horses (harnessed in line if two are used) are not attached to the head, but by a single chain to a staple on the beam of the plough near the breast. The adjustable head merely guides the chain. At first the ploughman, probably prejudiced against the novelty, finds it rather awkward, but he quickly learns to make the necessary adjustments, and can then handle the plough just as easily as an ordinary one, whilst he appreciates the comfort of walking clear of the branches. I have used the plough with success where there is only 6 feet of space between the rows of trees and Black Currant bushes, but it has done its best work in half a plantation of half-standard trees from which the bushes have just been grubbed, so that the rows of trees stand 12 feet apart, though they almost meet overhead in places. This ground was green with Twitch, but the plough has covered the grass completely, turning thin furrow-slices towards the stems of the trees, and leaving a shallow open furrow down the middle of the alleys, which gives capital drainage. The other half of this plantation, where the bushes are still standing, and are so big that there is no space for ploughing, is being forked by women. They find it impossible to cover all the Twitch, and the dug ground is still green with it. If desired

the plough can be set to plough away from the stems in spring, but I do not think this will be necessary, as the soil will be returned to the alleys sufficiently by the use of the horse cultivator and hand hoeing.

There are, of course, orchards that cannot be ploughed, as, for instance, where there are bushes between the rows of trees, and they have grown so large as practically to fill the space. Digging may be necessary for two or three years whilst this condition lasts, but the plough can be used instead for several years after the bushes have been planted and again after they have become worn out and are grubbed.

Pruning Neglected Trees.

On the ideal fruit farm all the trees would be pruned every year, but there are probably not many farms of any size where this is accomplished. The younger trees must be pruned, and this means that some of the older ones get neglected for a year or two for want of time or labour. As a matter of fact, trees that have reached a fair age, and are bearing freely but making little growth, can be left unpruned for several years without much harm. After a time, however, they begin to look decidedly neglected. Rank growths have sprung from the stem or main branches, and are taking most of the sap and growing up through the centre of the tree. There are also branches broken by the fruit-pickers, and dead wood, probably carrying some fungous disease.

I am dealing with several neglected patches this winter. It is slow and laborious work, particularly where there are many dead spurs to cut out, as is often the case with old Plum trees. High steps are needed, and there is none too much space to shift them about, and the work is much less interesting than the training of younger trees. However, there is great satisfaction in the smart and rejuvenated appearance of the trees when finished. The work is simple enough, though it requires some judgment. Beginners can be put to it rather than to the younger trees, though they are apt to do either too much or too little pruning. Thinning-out is the main object. I like to attack the tree first with the saw, cutting out any branches that are crowding the centre or resting upon others, as they often do after several crops have borne them down. Then the secateurs are used to remove smaller superfluous shoots and dead spurs. Labour in future years is saved by cutting shoots clean out or to a fruit-bud where possible. Shortening to a wood bud means the multiplication of shoots and necessitates annual pruning. Leaders hardly ever need shortening on old trees. The worst trees to prune are Apples that are badly cankered, and must have the diseased parts pared away and dressed with Stockholm tar, and Plums that have many dead spurs and shoots as a result of brown rot disease. All saw-cuts should be pared smooth with the knife and coated with Stockholm tar or one of the dressings sold for the purpose. The finishing touch is given by spraying with a caustic winter wash to remove the mossy growth which is generally to be seen on neglected trees.

Rabbits.

Complaints of rabbits gnawing fruit trees seem to be more general than usual this winter. This is peculiar, as the weather has been mild, and rabbits do not, as a rule, give much trouble until hard frost sets in. The barrier of tarred string, described in a recent article, has proved a failure. At first it seemed to be answering the purpose, but the rabbits have evidently become used to it, as they have again done much damage, in spite of renewed tarring of the string. Evidently the only efficient plan is the erection of a wire-netting fence round the plantation or a return to half-standard trees, which can have a 3-feet band of netting placed round the stem. Personally, I prefer the latter plan, as it is cheaper and altogether less troublesome. *Market Grower.*

ORCHID NOTES AND GLEANINGS.

ORCHID SALE.

At the sale of Orchids at Messrs. Protheroe and Morris' Rooms, Cheapside, London, on Friday, February 7, Mr. J. B. Slade, who presided in the absence through illness of Mr. H. G. Morris, said that this was the first of the sales of Orchids which it was intended to hold at frequent intervals throughout the year. Unfortunately the railway troubles prevented the sending of all the plants expected. The greater part of the lots submitted sold at fairly low prices, Dendrobiums and other popular kinds, useful for cut flowers, finding purchasers readily. The rarer kinds and small, unflowered hybrids, of which there was a good selection, commanded attention in proportion to their merits.

NEW HYBRIDS.

Mr. F. C. Puddle, gardener to W. H. St. Quintin, Esq., Scampston Hall, Rillington, York, sends flowers of two excellent hybrids. The one, Cattleya Merope, resulting from crossing Cattleya Trianae with C. Fabia (Dowiana aurea × labiata), while adhering closely to the best coloured forms of C. Trianae, is an improvement on that species, and evidently extends the period of flowering into the mid-winter season when flowers are most in request. The form of the flower is perfect, the petals and lip being unusually broad and well displayed. The sepals, petals, and tube of the lip are bright rosy mauve; the lip is purplish crimson, a series of bright lines extending from the base to the centre, which has a yellow blotch on each side.

Fig. 29.—Cypripedium Perseus.

CYPRIPEDIUM PERSEUS.

The fine form of this excellent hybrid illustrated in fig. 29, raised between C. Lady Dillon (Mrs. Mostyn × nitens Sallieri) and C. Alcibiades illustris (Leeanum giganteum × Monsieur de Curte), was shown by W. R. Lee, Esq., Plumpton Hall, Heywood, Lancashire (gr. Mr. Branch), at the meeting of the Royal Horticultural Society on January 14, and received an Award of Merit. The plant is one of the best of the C. Alcibiades crosses; the flower is of good shape, fine substance, and rich colouring. The dorsal sepal is pure white with heavy blotchings of dark claret colour, the spotting being lighter and smaller in size towards the outer part. The lip and petals are brownish-rose with a dark purple line up the middle of the petals and a narrow yellow margin at the edge of the labellum on the upper side.

Dendrobium Erota, two forms of which have been sent by Mr. Puddle, as its record would lead us to expect, shows signs of a reversion towards Dendrobium aureum, with improvement in size and substance. It was raised from seeds borne by D. chessingtonense (aureum × Wiganiae) crossed again by D. aureum. The flowers of both varieties are primrose-yellow, the labellum of one form having an orange disc with red-brown base and short, radiating lines, the other having the base entirely chocolate colour on a yellow ground, with lighter veining on the side lobes and margin. The D. nobile in D. Wiganiae is entirely eradicated, but the other parent—the yellow D. signatum—can be traced in the wax-like substance of the flower of D. Erota, although its bright yellow colour is toned to the lighter D. aureum.

WINTER FLOWERS.

I WAS interested in the lists of plants in flower in winter sent by your several correspondents, and especially the remarks by Mr. Rickards on p. 32 relating to Garrya elliptica. Here, at Fota, Queenstown, there are three specimens of Garrya elliptica, including male and female plants, and G. Thuretii, planted close to each other. Two trees to which I especially wish to refer stand side by side; in fact, touch one another.

Each winter the male plant of Garrya elliptica has its appearance spoilt by frost, the female plant suffering no damage.

The first-named suffers all over, and not only on the side caught by the sun, but inside the bush, where the growths get protection, the leaves and catkins are less injured. Until the end of last year the bush was a perfect picture; now, and for the past fortnight, its beauty has gone, whilst the racemes of flower and foliage on the seed-bearing plant are uninjured, also the catkins and foliage of G. Thuretii. At the present time the bush presents a more pitiable appearance than it did after the unusually severe winter of 1916-1917. I have read statements concerning the hardiness of this shrub, and that it does not need the protection of a wall. I am interested to know whether the plant here is an isolated case of a bush in the open, but well protected by the shelter of neighbouring trees and shrubs, being so tender. The variegated Abutilon vexillarum covering several feet of space on a wall facing south has many blooms open. A plant of Cytisus aeolicus on a west wall, with last year's growths a yard long, is freely studded with the white blossoms, defying injury by rains and sudden severe white frosts. On the same wall Acacia neriifolia is a mass of flower, and has been for the past two months, and is likely to continue in bloom for as long again. Azara microphylla is practically in full blossom in sheltered situations; Olearea stellulata has a great many fully expanded flowers; whilst Grevillea rosmarinifolia and G. juniperina (syn. sulphurea) are more or less always in bloom, as also is Teucrium fruticans. Another shrub in full bloom and absolutely hardy here is Hakea fugioniformis. Erica arborea some 12 feet high and well proportioned is getting quite white with flower. *E. Beckett, Fota Gardens, Queenstown.*

JANUARY FLOWERS AT LA MORTOLA.

READERS of the *Gardeners' Chronicle* may be interested in the enclosed list of plants flowering in the gardens in the open air at La Mortola, Ventimiglia, Italy, which I have just received from Mr. Joseph Benbow, the head gardener.

Acacia dealbata, A. cultriformis, A. Hanburyana, A. longifolia, A. Riceana, A. obliqua, A. podalyriaefolia, A. uncinella, *Abutilon striatum, Ageratum mexicanum, *Arbutus Andrachne, *A. Unedo, Aloe arborescens frutescens, A. a. natalensis, A. a. Milleri, A. a. Ucriae, A. caesia, A. ciliaris, A. comosa, A. longifolia, A. spinosissima, A. pluridens, A. Salm-Dyckiana, A. supralaevis, A. Winteri, A. rubrolutea, Agathaea coelestis, Anemone coronaria, *Berberis glauca, *B. asiatica, Billbergia speciosa, Bougainvillea Sanderiana, B. braziliensis, Buddleia auriculata, B. madagascariensis, Bouvardia leantha, Camellia japonica var., Caesalpinia Cacalaco, Cassia tomentosa and other species, Calpurnia aurea, Casuarina stricta, Celosia floribunda, Cercis Siliquastrum (a deciduous tree, which usually flowers before leaves appear, has flowered while the tree bore leaves—a most unusual procedure), Chimonanthus fragrans, *Citrus Aurantium (Orange), *C. Medica (Citron), *C. nobilis (Mandarin), Colletia spinosa, Coronilla glauca, C. valentina, Coriaria japonica, Correa Lawsoniana, Crassula lactea, Dodonaea viscosa, Datura arborea, D. chlorantha, D. sanguinea, Dahlia Imperialis, Diplopappus filifolius, D. fruticulosus, Echeveria coccinea, E. pachyphytoides and Echium giganteum, *Elaeagnus macrophylla, *E. reflexa, Erica arborea, Euphorbia splendens, Eupatorium grandiflorum, E. micranthum, *Ephedra altissima, Eriocephalus africanus, *Fatsia japonica, *Freylinia oppositifolia, Genista monosperma, Globularia Alypum, Grevillea glabrata, G. Thelemannianae, Gymnosporia buxifolia, Hakea laurina, H. suaveolens, H. varia, Hexacentris coccinea, Heliotropium peruvianum var's., Heteropteris aceroides, Hebeclinium ianthinum, Iberis semperflorens, Iris unguicularis and var's., Jasminum nudiflorum, J. primulinum, J. revolutum, Kalanchoe var's., Kleinia Anteuphorbium, K. Mandraliscae, Leptosyne gigantea, Lippia asperifolia, Lantana Camara var's., Lardizabala biternata, Lavandula abrotanoides, L. dentata, L. multifida, Lonicera Standishii, Montanoa bipinnatifida, M. mollissima, M. tomentosa, Othonna triplinervis, Olearia Forsteri, Osmanthus fragrans, *Oreopanax capitatus, *O. dactylifolium, *O. palmatus, *O. xalapense, Opuntia var's., Pteronia incana, Phylica ericoides, P. rosmarinifolia, *Photinia serrulata, Pandorea australis, Phaedranthus buccinatorum, Polygala apopetala, P. myrtifolia, Pittosporum bracteolatum, Passiflora actinia, *Rosa Banksiae and var's., R. sinica (Anemone), R. Bourbonia, *Raphiolepis indica, Reinwardtia trigyna, Rosmarinus officinale, Sparmannia africana, Senecio hadiensis, S. longifolius, S. Petasitis, S. grandiflorus, Statice macrophylla, S. macroptera, *Solanum auriculatum, *S. Hartwegii, *S. lanceolatum, *S. jasminoides, Spiraea myrtiloides, S. confusa, Sida mollis, Sphaeralcea umbellata, Streptosolen Jamesonii, Sempervivum arboreum, Tacsonia manicata, Templetonia retusa, Tecoma capensis, *Veronica Andersoni and var's., V. salicifolia, *Visnea Mocanera, Viburnum Tinus, Clematis cirrhosa, Halleria lucida, Monnina ciliolata, Narcissus var's., Dodonaea attenuata, Helleborus foetidus, *Peumus Boldus, and Vinca minor.

The majority of these plants are flowering in season, or approximately so, but those marked with an asterisk are phenomenally early, which Mr. Benbow attributes to the extraordinarily dry, warm autumn of 1918 on the Riviera. *Cecil Hanbury, Kingston Maurward, Dorchester, Dorset.*

FRUIT REGISTER.

THE HAILSHAMBERRY.

IN December of 1917 I treated one dozen plants of Hailshamberry, which had been moved in December, 1916, in the following manner, instead of transplanting them as usual.

With a draining spade a narrow trench about 15 inches deep was cut on each side of the row and about 16 inches apart. A cross trench was cut between each pair of plants, the trenches half filled with well-rotted farmyard manure, and the remaining space filled. The object of the trenches is to cut all runners whilst burying the manure, and the draining spade cuts them deeply with a minimum of labour. The old canes were pruned to the ground in January, 1918, and four shoots only were allowed to remain on each stool. The results were startling.

The canes grew about 7 feet high, and not withstanding the very unfavourable season, were smothered in berries. The fruit was deficient in sweetness owing to lack of sunshine, but was otherwise the best and largest crop I have ever seen of any kind of Rubus.

I am not prejudiced in favour of any particular variety, and am growing the above late Raspberry simply because I happen to have it, and because its crop is large, certain, clean, and of fine quality. I have yet to learn the effect of a very dry season. *T. of Kent.*

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Parsnips.—If the ground is in good, friable condition a sowing of Parsnip seed may be made from the middle of the month onwards, according to locality. Quarters that were occupied with early Celery will form an ideal position for this crop. The ground will be found well pulverised through the action of the weather, and all that will be needed now is a light forking over, adding, as the work proceeds, a good dressing of soot and burnt garden refuse. Smooth the surface with a garden rake, and draw drills a good inch in depth. Make the rows 18 inches apart. If exhibition roots are required the best results are obtained by boring holes 3 to 4 feet in depth at 18 inches apart, filling the holes with a finely sifted compost of loam, sand, and leaf-soil.

Onions.—The middle of this month is an excellent time for raising Onions in boxes. Crops treated this way are heavier and also more free from the Onion fly than those sown in the open. Sow the seed in a compost of sand, loam, leaf-soil, and a small amount of Mushroom bed manure, filling the boxes within an inch of the top. Make the soil firm and level, sow the seed and cover them with half an inch of fine mould. Stand the boxes in cold frames until the seeds germinate, then admit air on all favourable occasions, gradually hardening the seedlings, prior to planting them out during April. Water and syringe the plants only when needed.

Peas in Boxes.—Sow during the next four weeks a few boxes weekly under glass of the finer varieties of Marrowfat Peas. Heavy and even crops will be the result of adopting this method, whereas Peas sown outside early, particularly on heavy soils, are injured by insects and by frost. Sow the seeds rather thickly in boxes, and stand the latter in a cold house or frame; later on expose fully to the air, finally pulling them apart singly and planting them in zig-zag double lines, as one would plant Broad Beans. Duke of Albans, Quite Content, Alderman, and Criterion are suitable varieties for growing in this manner

Celery.—An early batch of Celery can be obtained if seed is sown about this date. Do not hurry germination unduly; a steady heat is all that is required. Sow the seed in pots, using a fine, sandy compost. Cover the pot with a sheet of glass, over which lay a piece of paper until germination has taken place, then expose the plants gradually to the light.

Lettuce.—Where good autumn-sown Lettuce plants are at hand, transplant them in sheltered positions, at 1 foot apart. Some of the more forward plants should be placed in a cold frame and encouraged by good, fertile soil and careful ventilation. Seed of suitable varieties should now be sown in gentle heat.

Tarragon, Mint, and Chives.—These herbs may be introduced into a warm pit or similar structure as required. If the Tarragon crop is short it can readily be increased by taking cuttings from the stools when the shoots are 2 inches long.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt.-Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cypripedium.—Many of the Cypripediums have passed out of flower, and if any are in need of repotting the present is the most suitable time for attending to them. A liberal shift should be given to root-bound plants, as the majority make roots freely. Use clean pots, and, if new, soak them in water for several hours previous to potting. About an inch deep of drainage material is all that is needed, and it should be properly arranged and covered with a layer of rough Sphagnum-moss, or peat, or loam fibre, to prevent the finer portions of the potting material from becoming washed down and block-

ing the drainage. The plants are best placed a little below the rim of the pot. The compost may consist of one-third part of turfy peat or A 1 fibre, one-third good, fibrous loam, and one third Sphagnum-moss and partly decayed leaves in equal parts, adding a good sprinkling of coarse silver sand, small crocks, and broken charcoal. Work the materials well among the roots, and pot moderately firmly. The larger the specimens the rougher should be the state of the potting materials — then further root-disturbance will not, perhaps, be needed for a year or two. If the potting compost is fairly moist watering should not be necessary for a week, then give a thorough soaking, after which, with extra care, until such times as the roots are growing freely in the soil. Copious supplies of moisture are needed throughout the season of active growth.

Platyclinis. Whilst neither of the two species of this small genus is generally met with in cultivation, P. filiformis and P. glumacea, possess any marked attraction in colour, they are, on the contrary, unsurpassed in the grace and elegance with which the flowers are displayed. The former species should be quite at rest during the winter months, its flowering time being about July. The latter species flowers in early spring, and should now be growing and developing its flower-spikes freely. Both species will thrive in the intermediate house, and delight in a liberal supply of moisture both in the atmosphere and at the roots during their active period. When the flowers are fully expanded the plants may be removed to a cooler house, where, if the atmosphere is moderately dry, they last in perfection a considerable time. The best time to repot Platyclinis is when the new roots commence to make their appearance from the base of the new growths.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to C. H. Berners, Esq., Woolverstone Park Gardens, Ipswich.

Melons.—Young Melon plants raised from seeds sown early in January and kept growing steadily in a position near the glass, will now be ready for planting out in the bed. The most suitable method of obtaining early Melons is by means of a bed of fermenting material placed over hot-water pipes. A steady and continuous bottom heat is necessary at this season; also the house must be thoroughly clean, and, if possible, free from drip. The fermenting material should consist of equal parts of stable manure and leaves. When forming the bed the fermenting material should be trodden very firm, particularly round the sides, otherwise it is apt to sink unevenly. A layer of turves with the grassy side downwards should be placed over the beds, and on these a ridge of soil built, composed of heavy fibrous loam, to which sufficient old lime rubble and wood-ash is added to keep the soil sweet and in a good open condition. If the soil is moderately dry when introduced into the house it may be rammed down very firmly to induce steady growth; should the soil be rather wet allow it to lay loosely in the ridge until its condition is suitable for hard ramming, without the risk of making it sticky and impervious to both water and air. When the temperature of the hot-bed has fallen to 85° the plants may be set out 2 feet apart. Tie each plant to a stake to hold it in position, and afford sufficient water at a temperature of about 80° to settle the soil around the roots. Maintain a night temperature of 65° to 70° (during severe weather a slightly lower temperature will be advisable), with a rise of 5° to 10° during the day. If protecting material is placed over the glass it will help to maintain an equable temperature without unduly heating the water-pipes. Melon seeds may now be sown for raising succession plants.

Tomatos.—The batch of earliest plants will now be ready for their fruiting quarters, either in pots, boxes, or borders under glass. A suitable compost consists of good loam to which is added a sprinkling of wood ash and a little old mortar rubble well divided; if the soil is somewhat adhesive, leaf-mould should be added. Make the soil very firm as planting proceeds. The plants should be placed as near the glass as may be convenient, and water should be applied sparingly until the roots are active. Maintain a steady temperature of 60°, a rather dry atmosphere, and afford free ventilation in mild weather. Sow seeds thinly in a light compost, and germinate them in a temperature of 65°. When the seedlings are fit to handle put them in 3-inch pots.

THE HARDY FRUIT GARDEN.

By James E. Hathaway, Gardener to John Brennand, Esq., Baldersby Park, Thirsk, Yorkshire.

Draining.—It is of the utmost importance that land for fruit-growing should be drained efficiently of superfluous moisture. Some soils allow water to pass through them freely, but others do not, and in consequence such ground at certain seasons is very cold and wet. Cold, undrained land causes the atmosphere about it to be damp and chilly, and this condition is often the cause of fruit-blossom being destroyed by frost in spring, whilst the wood does not ripen so readily in the autumn. Certain soils have a natural free drainage, but where any doubt exists as to the free passage of water a simple method of ascertaining is to dig holes about 4 feet deep and about 30 yards apart in the autumn, cover them to keep out surface-water, and if water is found in them, or they fill with moisture that remains for more than a week, then it is necessary to put in drains. Stone or tile drains may be used; I recommend tile drains, as they are the cheapest and best. Before commencing the work choose a suitable place for an outlet at the lowest level of the ground. The land should then be levelled from this point, using a surveyor's level or rods. The latter is a simple method, and consists in having three rods, each 4 feet long, 3 inches wide, and about ½ inch thick, with cross-pieces 13 inches wide and 4 inches deep nailed on the top. The cross-pieces should be painted white, and the one to be used at the farthest point should have a red line about ¾ inch wide painted on the top to catch the eye. A broad peg should be driven in the ground level with the surface at the point of outlet and a length of about 15 feet should be levelled with a straight-edge and spirit-level. Next insert a peg at the end, place one rod on each peg, and by looking over these the third rod can be lowered until its top is level with the others. It may be necessary to take another straight-edge length from the point of the last peg; by this method a fairly accurate estimate of the amount of fall can be made. After ascertaining the amount of fall a main 6-inch drain (4-inch piping may be used for less than 5 acres) should be inserted. This main drain should run along the lowest point of the land with enough slope to give it a fall to the outlet. All minor drains should enter the main drain diagonally in the direction the water runs; they should not be put in at right angles. Minor drains may be of 2- or 3-inch pipes; I prefer those of 3-inch diameter. The depth at which the drains are placed varies with different soils, and should not be nearer the surface than 3 feet nor deeper than 4 feet. The reason I advise a depth of 3 feet is that 2 feet of soil is needed for the roots of fruit trees, and another foot below that should be free of stagnant water; moreover, drains, say, 2 feet deep are liable to become blocked with the roots of the trees. In laying a drain where there is ample fall a good plan is to take out a length of 15 to 20 feet, and if there is no water in the trench, by pouring some in, the direction of fall will be ascertained. Where there is only a slight fall it is best to use a spirit level on each pipe. In filling the trenches where the soil is of a clayey or sticky nature first cover the pipes with broken bricks, stones, or clinkers, to within 1 foot of the surface, otherwise the soil will settle around the joints of the pipes and render them useless. Where sand is present in the soil it is a good plan to cover the pipes with straw before filling in the trench, as this prevents the pipes silting up for a long time. The distance of side-drains must be determined by the nature of the soil; in the case of very retentive soil they should be placed 12 feet apart, and for sandy soils up to 30 feet apart. The outlet should have an iron grating placed in front to keep out animals. Draining tools, consisting of three different-sized spades, a drag and pipe-layer, should be used: these spades are made narrower than ordinary spades and enable the work to be done more expeditiously.

THE FLOWER GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet, Hertfordshire.

Lobelia.—If Lobelia compacta is to be raised from seed instead of propagated from cuttings, for bedding purposes, the seed should be sown during the present month. If the plants are given reasonable attention they will develop into sturdy specimens, regular in height. Sow in pans containing sweet, gritty soil pressed rather firm, and be very sparing with water until after the plants attain a reasonable size.

Hollyhock. — Seed of both the double and single varieties of Hollyhock may be sown forthwith and, if the seedlings are duly attended to, good plants will be ready to plant out in deeply-cultivated land that is in good heart. Sow the seeds in a well-drained pot or seed-pan filled with sweet soil well mixed with grit, and germinate them in a temperature of 60°.

Thinning and Transplanting Shrubs.—Where shrubberies have become very crowded there is still time to carry out the work of thinning with good results, notwithstanding that the best time for removing large plants is in the autumn. Very choice plants should be carefully lifted with a large amount of soil adhering to the roots, and the planting should be completed at once in sites previously prepared for their reception. Use plenty of soil, work it well amongst the roots, and ram it moderately firmly. After planting place over the root area a good mulch of decayed manure and litter.

Pruning Trees.—The work of pruning may be carried out whenever the weather is suitable. Keep the heads of the trees as symmetrical and graceful as possible, and prune so that there is practically no evidence of the use of saw and knife.

PLANTS UNDER GLASS.

By James Whytock, Gardener to the Duke of Buccleuch, Dalkeith Palace, Midlothian.

Chrysanthemum.—In all stages of its development the Chrysanthemum should be grown in cool conditions. A good method of rooting the cuttings is to insert them in a propagating frame placed near the roof-glass in a house with a temperature from 40° to 50°, the bottom of frame sprinkled with fine coal ashes. Cuttings inserted early singly in small pots for the purpose of raising plants producing large blooms are rooted, and should be shifted into 4-inch pots. The soil should consist of two parts good loam, one part leaf-mould, mixed with manure from a spent Mushroom-bed and sharp sand. Place the plants on a shelf near the roof-glass in a cool house. Cuttings inserted in three or four 3-inch pots for raising plants to produce cut blooms and for decorative purposes are rooted, and should be shifted into 5-inch pots and placed on a shelf. For economy of space, cuttings rooted in a warm house on a slight hot-bed should, as soon as rooted, be potted, three or four in each 4-inch pot, placed in a warm house until their shoots are rigid, then removed to a cool house in a position near the roof-glass. Cuttings of the latest flowering varieties may still be inserted.

Decorative Pelargoniums. — These plants should be finally potted in small receptacles. Pot firmly, using rich loam, mixed with a plant fertiliser. Place the plants in an airy, well-ventilated house near the roof-glass. Water the roots with extra care until growth is established, and keep the plants clean from green fly by occasional fumigations.

Conservatories and Flower Houses.—With a little warmth it should not be difficult to keep the houses gay with subjects that require only mild forcing, such as bulbs of Narcissus, Crocus, Scilla, Lilacs, Azalea indica, A. mollis, Deutzia, Spiraea, and Lily-of-the-Valley, all of which respond readily to a little warmth. Camellias, where planted in borders, may be hastened into flower with a little warmth, giving the roots occasional waterings with manure-water. Forced plants that have finished flowering should be picked over, placed in heat, and syringed daily, to have them in suitable condition for forcing next season.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 17—
Nat. Chrys. Soc. Executive Com. meet. at 35, Wellington Street, Covent Garden, W.C., at 6 p.m.

THURSDAY, FEBRUARY 20—
Manchester and N. of England Orchid Soc. meet.
Brighton Hort. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.5°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, February 12, 10 a.m.: Bar. 30.3; temp. 34°. Weather—Sunny.

Prohibition of Imports of Plants into the United States. British horticulturists have learned with great surprise and regret that the United States proposes to prohibit, as from June 1 of this year, the importation of many kinds of plants and bulbs. This decision will affect very seriously those members of the horticultural trade in this country who had made it their business to supply the requirements of America. They have devoted many years to building up this business, and certain of the plants which they raise for this purpose are of slow growth; these nurserymen have, therefore, sunk a considerable amount of capital in it. Now, peremptorily and without warning, it is declared that the American ports are to be closed to their produce. It is to be hoped that vigorous representations will be made by the Government of this country, and that the hardship due to the suddenness of the decision will be urged with the object of securing at least a delay in putting the regulation into practice. It is said—we cannot believe either authoritatively or seriously—that the object of the regulation is to guard the United States against the immigration into that country of pests in the shape of insect or fungous diseases which might do damage to the cultivated plants already growing there. Although each nation must be a law unto itself with respect to its fiscal policy, all nations have an interest in securing that each shall act according to the dictates of common sense and with regard to the teachings of science. We are unable, therefore, to believe that we can be correctly informed with respect to the reasons which have led to the prohibition it is proposed to enforce. For it is quite certain that, whatever other effect it may have, it will not prevent the arrival of pests in America. To prevent this, the absolute exclusion of all vegetable produce would be necessary; for example, the American Bureau of Plant Industry, which has done such admirable work in introducing from all parts of the world plants of economic potentiality, would have to stop its enterprise. So long as it continues, no member of the U.S.A. Federal Board of Horticulture would be able to sleep in his bed without the chronic nightmare of the possible introduction of some pest on the earth attached to the roots of the plants which the Bureau collects from all parts of the world, not excepting British Possessions. It is a grimly ironical fact, on which we have commented more than once, that the plant pathologist, who, in so far as he is concerned with horticulture at all, has as his main duty the discovery of remedies for plant diseases, is so modest of his own powers in this direction that he is often among the first of those who clamour for restrictions on the free exchange of living commodities. We are of opinion that in adopting this course of action as a means of excluding chance pests the pathologist takes the narrow instead of the broad view. The United Kingdom has suffered much from introduced American plant pests, but it is probable, nay, certain, that the advantage which this country has gained by the introduction of the plants which bore those pests is many hundred times greater than the disadvantages. Decisions arrived at by a State have to be respected, even though they press hardly on other communities; but it may be said without fear of contradiction that if this particular decision is based upon a desire to exclude pests, it is a wrong decision, and one which will press at least as hardly on the horticulturists of the United States as upon those of Europe. We would, therefore, urge our colleagues in America to use all their influence in pressing for an immediate reconsideration of this question.

Royal Agricultural Society's Show. — The Royal Agricultural Society of England has arranged to hold a show at Cardiff on June 24 to 27, 1919. A horticultural section will be included under the management of Mr. PETER BLAIR, Trentham, Stoke-on-Trent.

National Standard of Hours and Wages for Gardeners.—The following standard of hours of work and wages has been adopted by the British Gardeners' Association, and the Association will endeavour to obtain this standard throughout the country. Members of the Association are reminded that the wage rates are minimum, and are advised not to accept fresh situations at terms under these rates. The General Secretary (Mr. CYRIL HARDING, 22, Buckingham Street, W.C.) will welcome information as to conditions prevailing in local areas throughout the country. Private gardens:—In all districts the prevailing county agricultural rate has been selected as a basis for fixing the standard. Juniors: 2s. 6d. per week above mimimum county agricultural rate up to age when minimum rate for adults begins to apply. Adults: Less than 12 months' experience, 2s. 6d. per week over county rate; exceeding 12 months' experience, 5s. over county rate; exceeding 7 years' experience, 7s. 6d. over county rate. Foremen: 15s. over county rate. Head gardeners and single-handed gardeners: 30s over county rate. Hours: 52 in summer, 48 in winter. Overtime: Time and a quarter ordinary working days; time and a half Saturday afternoons, Sundays, and holidays. Market nursery workers.—Hours and overtime: In all cases as for private gardeners. Workers: Over 3 years' experience, 45s. Charge hands: 55s. These rates to apply to workers over the age when the minimum county agricultural rate begins to apply. Juniors: Up to county rate age, 2s. 6d. above agricultural minimum. In nurseries.—Workers up to foremen: Same rates as laid down for private gardeners. Departmental foremen: 60s. per week. Jobbing gardeners: The sub-committee does not think it advisable at the present time to fix a definite scale of rates for jobbing gardeners. In public parks and gardens.—Boys and improvers: 15 years, 22s. 6d.; 16 years, 25s. 6d.; 17 years, 27s. 6d.; 18 years, 30s. Under gardeners: 18 to 21, 30s., rising to £2; over 21, £2 10s. Foremen: £2 15s. to £3 5s. minimum, according to responsibility.

Sweet Pea Annual for 1919.—Through good and through evil years the National Sweet Pea Society has continued the publication of its "Annual," and the issue is regularly looked forward to with great interest by all who have an enthusiastic regard for the Society's elegant and fragrant name-flower. The "Annual" for 1919 is devoted very largely to a consideration of Sweet Peas as grown for flowers or seed in the United States, New Zealand, New South Wales, and Nova Scotia. Home news is confined to the Society's annual report and accounts, descriptions of new Sweet Peas, too-much-alike varieties, and the suggestion to form a branch of the N.S.P.S. in Scotland. The contents are interesting and instructive, and their international character indicates the widespread love of the flower HENRY ECKFORD did so much to improve and bring into popularity. The price of the Annual to non-members is 2s., post free.

M. Ed. Godard.—We learn but now of the death, on April 26 of last year, of M. ED. GODARD, whose coloured drawings of plants were for long so valuable a feature of the *Revue Horticole*. M. GODARD'S work began in 1877, and continued until 1902. His accurate drawings form the major part of *l'Album des Clichés* of Messrs. VILMORIN. M. GODARD was a man of exceptional modesty but of ardent patriotism; he took part in the defence of Paris in 1871. He bequeathed all his possessions to the Paris Natural History Museum and to the Observatory.

Celebrated Trees.—Great Britain's wonderful and unrivalled collection of exotic trees was the subject of a delightful lecture given recently by Mr. HENRY J. ELWES, F.R.S., before the Gilbert White Fellowship. He referred to the fact that since LOUDON'S days there had been no systematic collection of records of such trees and of their growth; but in justice to the lecturer it must be interpolated that dendrologists are indebted to him more than to anyone else for the very considerable work which has been done in this direction. The race of naturalists of which Mr. ELWES is a distinguished member still flourishes in this country, and there are signs that the laboratory botanists are getting a little disillusioned of their belief that theirs is the oracle that alone can whisper the secrets of Nature. Mr. ELWES did well to recount to this commercial age the story of

Inspection of our **Model Block of Houses** devoted entirely to **Orchids** invited.

Thousands of **Choice Hybrids, Albino Orchids,** and **Rare Species** to select from.

Advice given about the Erection and Management of **Orchid Houses,** and questions relating to **Orchids** promptly replied to.

Tunbridge Wells Station, 1½ mile.

ROSES IN POTS

For Forcing or Greenhouse.

HYBRID TEAS,

Choice varieties, strong healthy plants, in 6 to 8-inch pots, at 36/- to 48/- per dozen

WICHURAIANAS,

Extra strong, with many shoots, fine for Pergolas, 8 to 12-inch pots, 60/- to 84/- per dozen.

CLIMBERS IN VARIETY, 36/- to 48/- per dozen.

OPEN GROUND

A large collection in all the leading varieties of H.P.s, Hybrid Briars, Moss and Climbing Roses.

THOMAS RIVERS & SON,
Sawbridgeworth.

ESTATE PLANTING.

WE offer for early delivery the following well-rooted transplanted stuff at special prices to clear the ground.

CRICKET BAT WILLOW.

Salix alba caerulea. The quickest growing, most profitable and best variety. See notes on page 53 *The Field*, January 11th, 1919.

Extra strong well-rooted setts, 3-years, 8-10 ft., 12/- doz.; 90/- per 100.
Stout 2-years' rooted setts, 5 6 ft., 9/- doz.; 70/- per 100

BEECH.—Common, 3-4 ft., 12/- per 100; 100/- per 1,000
HAZEL.—Strong and well rooted, 7/6 per 100; 65/- per 1,000
PRIVET.—Oval-leaved variety, good, transplanted. 3-4 ft., 12/- per 100; 100/ per 1,000
SYCAMORE.—Good straight trees, transplanted 1917, 8-10 ft, 65/- per 100
SPRUCE.—Transplanted Spring, 1918, 1½-2 ft., 7/- per 100; 60/- per 1,000
THORNS or QUICKS.—Splendid strong stuff for gapping, 3-4 ft., 10/ per 100; 90/- per 1,000

Samples on Application.

EDWARD WEBB & SONS (Stourbridge), LTD.
The King's Seedsmen. STOURBRIDGE.

Lord BAGOT, told him on a visit to Bagot's Park, Staffordshire, famous for its Oaks. Asked why he did not relieve his relative penuriousness by disposing of his timber—the Oaks were estimated to be worth £50,000—Lord BAGOT replied : "The BAGOTS are not timber merchants."

Mahogany.—Mahogany! How many woods are worked under thy name? Prof. DIXON enumerates* no fewer than 45 kinds of timbers which take the names belonging to Swietenia Mahagoni and S. macrophylla not commercially in vain. At the present time it is doubtful whether any Mahogany comes from either of the regions in which these species grow; the former is found in Cuba and St. Domingo, the latter in Honduras, Tabasco, and Columbia. Prof. DIXON, on the basis of his microscopic examination, suggests as a definition of Mahogany—all red or red-brown timbers in which the fibres of adjacent layers cross obliquely.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Rosa Moyesii.—In *Gard. Chron.*, February 1 (p. 56) *A. B. B.* raises several interesting points in connection with Rosa Moyesii. It is unfortunate for the reputation of this magnificent Rose that some (horticulturally) worthless varieties or sub-species are in cultivation. These are almost indistinguishable from the real plant except when in flower, for the foliage and fruits are practically identical. I have had two of them growing close to a plant of the first-rate type, so there can be no question, I think, of cultural differences being responsible for their inferiority. The genuine plant is a good, strong grower, and it likes (with me) a rich, stiff loam, and a damp situation. Every year after flowering it receives a good mulch of manure, and last year the bush, which is about six years old, produced a number of new shoots from the base, the largest of which is about an inch in thickness at 1 foot from the ground, and about 10 feet long. Every year all the shoots are wreathed with splendid blossoms along their whole length, and the flowers, the best of which are 2 inches or more in diameter, are of that gorgeous red colour which I have never seen in any other species of the flowering plant. The fruits, which are very handsome, are very freely produced, but I strip most of them off whilst they are still young, in order to prevent undue exhaustion of the plants. This Rose is not too easy to propagate, but I find cuttings root fairly freely in pure sand. It would be interesting to know what the experience of others is on this matter of propagation, for I am far from thinking I have hit on the best method. Can any of your correspondents say whether it grows readily from seed? I have tried it for several years, but with unsatisfactory results. *J. B. F.*

Women in Horticulture.—On page 247, Vol. LXIV., *W. W.* refers to the advent of the woman gardener at Kew 23 years ago, and reviews her progress up to the present time. In his concluding paragraph he sums up "with the conviction that unless the conditions are considerably improved, gardening will not hold out good prospects for educated young women." I entirely agree with that statement, and after a fairly varied experience of women labour during the past four years, I have come to the conclusion that few head gardeners wish to see them remain in the profession—not altogether because the conditions are unsuitable, but because, speaking generally, women have proved to be unsuitable for gardening. This may be regarded as merely male prejudice, but it is not. In pre-war days I was under the impression that there was a wide field for women in gardens, and the war gave them a great opportunity, but I feel convinced now that women will never be serious rivals to the men and boys of pre-war days. There are various reasons for this; in the first place, the so-called training given in many horticultural colleges and schools leaves much to be desired, and it is practically useless in the average garden. A vast amount of hard work is necessary in most establishments if the garden is to be a success, but one finds that in many cases young women have been told by their doctors (very often after a serious breakdown in health at other work) that gardening would be a very suitable occupation. One can scarcely blame the young women if this appeals to them, but is it fair to the employer, to find that these young women (who are usually extremely enthusiastic and loud in their pronounced love of trenching and other strenuous work), are absolutely physically incapable, not only of trenching, but of any real or sustained effort, such as is constantly required of all persons, male or female, employed in gardening on strictly business lines? Not 10 per cent. of the women who start gardening will be found in it after a very few years' experience, and, personally, I have met with very few who regard it seriously: in fact, I think one of the principal reasons of the apparent failure to make headway in gardening is that they enter on it too lightly. I have met a few brilliant exceptions of women gardeners who were striking successes, but they usually express themselves as very disappointed with the work of the majority of women who have rushed into gardening. *Dubious.*

FIG. 30.—SWIETENIA MAHAGONI : THE MAHOGANY TREE.

Apple Edward VII. (see pp. 21, 56).—I have grown this Apple here for several years, and although several of your correspondents have praised it, I have failed to get good results from it. The fruit also cracks very badly when it starts to swell. The subsoil of these gardens is a heavy clay, and perhaps that fact may account for the variety not doing well with me. *T. Pateman, Node Gardens, Welwyn.*

* Sci. Proc. Royal Dublin Society, XV., p. 431.

SOCIETIES.

ROYAL HORTICULTURAL.

February 11. The wintry weather prevailing on this date and for a week previously was chiefly responsible for the small attendance at the Royal Horticultural Society's meeting at the London Scottish Drill Hall, and for the paucity of exhibits. The Narcissus and Tulip Committee met for the first time this year, but its business consisted only in passing previous minutes and signing the attendance book. The Fruit and Vegetable Committee spent some time discussing the merits of seedling Apples, but the only award made in this section was a Silver Knightian Medal. The Floral Committee, kept out of its usual meeting-room by a burst pipe, conducted its small amount of business in the body of the hall: no novelties came before it, but three medals were awarded to groups. Although Orchids were far less numerous than usual the Orchid Committee had to inspect numbers of novelties and granted six Awards of Merit.

Garden plans and paintings and drawings of flowers added to the interest of the meeting, but of even more interest than these were the photographs showing Melons, Chrysanthemums, Rose beds, Daffodils, Sweet Peas, displays of vegetables and other crops grown at Ruhleben camp by the members of the Ruhleben Horticultural Society: a framed and illuminated testimonial to the Royal Horticultural Society occupied a position of honour. It was worded as follows: "Ruhleben Horticultural Society. — We, the committee and members of the Ruhleben Horticultural Society, desire to express to the Royal Horticultural Society and friends at home our heartiest thanks for the valued gifts and generous support which have made possible our work in Ruhleben. We request the acceptance of this testimonial as a token of our gratitude and appreciation."

Floral Committee.

Present: Messrs. Henry B. May (in the chair), C. Dixon, John Heal, J. W. Barr, W. Howe, George Paul, C. R. Fielder, H. R. Darlington, E. H. Jenkins, W. J. Bean, W. H. Morton, J. Jennings, A. Turner, G. Reuthe, Andrew Ireland, John Dickson, H. Cowley, Clarence Elliott, Thos. Stevenson, and E. F. Hazelton.

Groups.

Small specimen plants and cut branches of a large number of conifers submitted by Messrs. J. Cheal and Sons commanded attention by reason of the extent of the exhibit, which contained representatives of 160 species and varieties. The collection was especially rich in Pines and Abies, and contained such dwarfs as Abies balsamica hudsonica, Picea orientalis nana, and P. excelsa Remontii, as well as a number of Golden Cupressus. (Silver-gilt Banksian Medal.) Daffodils, blue Primroses, Polyanthuses, and Iris reticulata combined to make a bright exhibit from Mr. G. W. Miller. (Silver Banksian Medal.) Well grown and freely-flowered Cyclamen, representing a good strain, were displayed in a fair-sized group by Messrs. Barr and Sons, and gained a Silver Flora Medal.

About a dozen and a half seedling varieties of Freesias raised and shown by Messrs. Herbert Chapman proved very interesting, especially as indicating the range of floral colouring now possible in this genus. Very dainty were Lavender Queen, Sepia, and Mother-o'-Pearl, while Aurantiaca and Gilt-Edge were brighter and larger. Messrs. S. Low and Co. sent a few cut blooms of Perpetual Carnations.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, R. A. Rolfe, W. Bolton, Frederick J. Hanbury, R. Brooman-White, C. J. Lucas, J. Charlesworth, Chas. H. Curtis, S. W. Flory, Fred. K. Sander, Pantia Ralli, and J. E. Shill.

AWARDS.

Awards of Merit.

Odontoglossum Empire (*eximium* × *Marathon*), from Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells. — A very large and beautifully marked flower, with broad segments closely blotched with claret-red on the inner two-thirds, the blotches having intersecting lines of white. The outer parts of the segments are blush-white.

Odontoglossum crispum The Marquis, from Messrs. Charlesworth and Co., Haywards Heath.—A very charming home-raised variety, pure white and of fine shape, the petals and lip being finely fringed.

Odontoglossum Radians (*Dora* × *Alexandra*), from Messrs. Charlesworth and Co.—A fine variety of the cross reported in *Gard. Chron.*, Feb. 1, p. 57. The present variety had very large flowers with rosy-mauve ground-colour profusely spotted with dark claret colour.

Odontoglossum St. George (*eximium* × *Alexandra*), from Messrs. Charlesworth and Co.—A fine flower, the white ground blotched with dark mauve. The bases and tips of the segments are white.

Odontoglossum Gatton Emperor var. Tiberius (*Lambeauianum* × *hybrid unrecorded*), from Sir Jeremiah Colman, Bart., Gatton Park, Surrey. —The darkest of the violet-coloured type raised at Gatton, several forms of which have been already shown. The present variety had flowers of good form, and of a uniform violet colour with blush white tips to the sepals and lip.

Brasso-Laelio-Cattleya Imogen (*L.-C. Trimyra* × *B. C. langleyensis alba*), from Messrs. Flory and Black, Slough.—A very desirable hybrid, and one of the few Brassavola crosses retaining the large-flowered Cattleya shape. The flower is of excellent form, pure white, with chrome-yellow disc to the lip, which has a pretty fringed margin.

Cultural Commendation.

To Mr. Farnes, Orchid grower to Pantia Ralli, Esq., Ashtead Park, Surrey, for a fine plant of Cymbidium Gottianum (insigne × eburneum), with six spikes, bearing together twenty-five flowers.

Other Exhibits.

Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, showed a selection of new hybrids which included Odontioda Flambeau (Oda. Cooksoniae × Oda. The Duchess), with fine cinnabar-scarlet flowers; Oda. Victory (Oda. Henryi × Odm. amabile), with white ground marked with deep maroon and having violet margin; Oda. Joan, Orchidhurst variety, entirely dark scarlet; Odontoglossum Alcibiades, a fine flower which had previously secured a Preliminary Commendation, and Odm. Columbine.

Messrs. Charlesworth and Co. included in their group of novelties Odontoglossum Faustina (Dora × eximium), rich claret colour with lilac tips and margin; a selection of very fine home-raised Odontoglossums, and several promising Odontiodas.

Messrs. Flory and Black, Slough, showed three plants of the pretty white Cattleya Douai (intertexta alba × Suzanne Hye de Crom); the finely-marked Odontoglossum Pallas (illustrissimum × Doris), and Odm. Portia (illustrissimum × Aglaon), a flower of good shape and effective marking.

Messrs. Sanders, St. Albans, staged a small group, the finest novelty in which was Odontioda St. André (Oda. Sanderae × Odm. amabile), with a fine spike of perfectly-formed flowers, densely blotched with orange-scarlet. The yellow Cymbidium Capella var. Orange Prince, and the rare Cypripedium Sanderae, were also shown.

Baron Bruno Schroder, The Dell, Englefield Green (gr. Mr. J. E. Shill), showed three flowers of varieties of his superb strain of Cypripedium Eurybiades The Dell variety.

Narcissus and Tulip Committee.

Present: Messrs. E. A. Bowles (in the chair), Chas. H. Curtis (hon. sec.), Col. H. Warrender, F. Herbert Chapman, and P. R. Barr.

There were no exhibits before this meeting.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), J. Cheal, Owen Thomas, E. Beckett, E. Harriss, P. T. Tucker, A. Bullock, A. R. Allan, A. W. Metcalfe, F. Jordan, E. A. Bunyard, W. H. Divers, S. P. Berry, W. Bates, W. Poupart, and W. E. Humphreys.

A capital display of winter vegetables made by Messrs. Sutton and Sons was a reminder of the variety of foodstuffs obtainable from a well-arranged kitchen garden at this season of the year. The exhibit included Brussels Sprouts, Savoys, Cabbages, Kohl Rabi, Carrots, Parsnips, Onions in variety, Beet, Swedes, Turnips, winter Radish, Leeks, Kales, Salsafy, and Celery. (Silver Knightian Medal.) Mr. W. Peters, Givons Park Gardens, Leatherhead, sent samples of Bedford Champion, Ailsa Craig, and Nuneham Park Hero Onions.

The bottled and dried fruits and vegetables set up by Mr. Vincent Banks, who has been chief instructor to the Food Production Department in the art of treating surplus fruits and vegetables for winter use, were of special interest, as the exhibit, of about one hundred and fifty bottles, constituted the "travelling exhibit the Board of Agriculture is prepared to send, in charge of an expert, to horticultural food production and similar exhibitions in various parts of the country, on application."

Annual Meeting.

In the unavoidable absence of Lord Grenfel and Sir Harry J. Veitch, Sir Albert Rollit presided over the annual meeting, held at 3 p.m. in the Council Chamber. There was a moderate attendance, and among those present were Sir J. Llewellyn, Capt. Hill, Rev. W. Wilks, Major Nix, J. Cheal, A. Sutton, E. A. Bowles, H. B. May, Jas. Hudson, F. J. Hanbury, W. H. Divers, W. H. Page, W. A. Bilney, W. Hales, and M. Allwood.

Seventy-one new Fellows, nine Associates, and fourteen affiliated Societies were elected.

In moving the adoption of the Report Sir Albert Rollit said it was the best Report ever presented to the members, as it gave ample evidence of hard and excellent work accomplished by the Society's staff, and told of national service rendered by the Society in connection with food production. Sir Albert referred to the Society's publications on allotment gardening, to its expert lecturers, its food production exhibits sent to various parts of the country, and its panel of 2,000 gardeners. So excellent was the programme arranged and carried out by the Society that it had been imitated by the United States, which was a great compliment. Sir Albert considered the educational work of the Society throughout the country and at Wisley deserved the heartiest support, and in this connection he referred to the Lindley Library, which was essential to horticulture and of immense value to the Fellows and in no sense a luxury.

Sir John Llewelyn seconded the motion, and thanked the Council for having moved the Sugar Controller to allow private growers to have sugar for preserving their home-grown fruit.

Mr. Arthur Sutton was then presented with the Lawrence Medal, awarded for a series of special exhibits illustrating the success and value of late-sown vegetable crops. Sir Frank Crisp could not be present to receive the award of the Victoria Medal of Honour in Horticulture.

Mr. C. Harper reviewed the accounts, and said that notwithstanding all the educational work carried out by the Society in 1918, a surplus of £4,000 remained at the end of the year, even after the expenses of the Wisley Gardens had been met. Major Nix moved the adoption of the accounts, and they were accepted.

The chairman declared the president, vice-presidents and retiring members of Council duly elected, as there were no other nominations and therefore no need for a ballot.

Mr. W. A. Bilney formally moved that a declaration of the aims of the Society be placed at the head of the bye-laws, and that all "shows" should be called "meetings," such meetings to include lectures and exhibits of a scientific and educational character. It was agreed that the addition and amendments be made

At the request of the chairman M. Georges Truffaut gave a brief account of the work of food production carried out in army gardens in France, firstly of the French military authorities under his direction and secondly by the British Army. There were, he said, 56 nursery gardens and 70,000,000 vegetable seedlings were grown at Versailles alone for the supply of the army gardens, while the total number of vegetable seedlings raised was not less than 250,000,000, by

means of which the food supply of the armies had been enormously improved and increased. He thanked the R.H.S. on behalf of the French people for the great help it had given to France through the War Horticultural Relief Fund, but he expressed sorrow that some of the work would have to be done over again, as, in the case of 15,000 young fruit trees planted to replace trees destroyed by the Germans, the Huns again overran the new planted districts and lifted and conveyed the young trees to Germany.

Having announced that the Society would hold a "meeting" at Chelsea on May 20, and that probably the Society's Hall would be available for the fortnightly meetings about three months hence, Sir Albert Rollit was accorded a vote of thanks for presiding.

EXTRACTS FROM THE REPORT OF THE COUNCIL.

In issuing the one hundred and fifteenth Report of the Society, the President and Council feel that they have very great cause to congratulate the Fellows, not only on the conclusion of the most terrible war which this country (or indeed any other country) has ever had the misfortune to have been forced to engage in, but also on the fact that, notwithstanding the financial strain which has fallen upon all classes of the community, the Society has been able to weather the storm, and even, in this last year, to restore, to some slight extent, its numbers, which the first year of the war had so greatly depleted.

The Society has spent over £2,500 during the year on its Food Production work, for which a grant is being given by the Treasury through the Food Production Department.

Whether the present allotments can in all cases be continued depends on many different considerations, but the Council are unanimous in expressing their opinion that so far as accessible land can be found, an allotment garden ought to be available for every man in this country who, having no garden attached to his dwelling, desires one; and that the provision of them ought to be made out of national funds, and with fairness and even generosity towards the present land-owners. The President and Council are convinced that such provision of national allotment gardens to all who desire them and work them well, will be of inestimable value to the country at large in promoting the health, happiness, and well-being of the community in general.

The Society's war publications, pamphlets, and leaflets have continued to be in demand. After the very heavy issue of 1917 and the first four months of 1918, it was no little relief to the office staff to know that their immediate purpose had in the main been accomplished, and some little falling-off from the previous demand for them gave welcome relief from the heavy strain which the Publications Department had borne during the previous months.

The Lindley Library has been maintained in a state of efficiency, and though the number of horticultural books put on the market during the war has not been so great as before, no opportunity has been lost of acquiring any valuable books which have been offered.

Seeds and bulbs were again sent to our fellow-countrymen prisoners in Germany, and to camps and hospitals in France and in the Mediterranean regions.

The work at Wisley, as in all other gardens, has been greatly handicapped by shortage of labour and the absence on special Government war-work of almost the whole of the laboratory staff. The difficulty has been met to some extent by the elimination of all trials of flowers for the period of the war, and by postponing all new developments in the Garden.

The vegetable trials, which are such an important feature of the Society's work, have been continued, and a number of trials of plants of possible garden value have also been made, some of them at the request of the Food Production Department of the Government.

Of cultural experiments made in the Garden during the past year special mention may be made of planting to ascertain the most economical method of spacing Parsnips and Potatos. Tests of the value of "sludge" manures, and of organic manures as compared with chemical fertilisers, have also been made. The experiments on the pruning of fruit trees are being continued, whilst many of the new crosses of Vines, Strawberries, and Rubi raised in the Gardens should fruit next season and show their value.

Mr Ramsbottom, who has now taken up a new position, was able to carry out another season's work upon the eelworm disease of Narcissi, a report of which will be published in the Society's *Journal*. Mr. Ramsbottom has consented to continue this investigation till its completion.

Dr. F. V. Darbishire, M.A., has been appointed to carry out researches into the comparative composition of different varieties of the same vegetable, in order to ascertain whether one variety is of greater food value than another, as appears probable. He took up his duties in August. Mr. Ramsbottom's place has been filled by Mr. A. J. Rudge, an old student at Wisley.

The Food Production work of the Society has undoubtedly brought it into wider relationship with the country at large. This has recently been made manifest in many ways. One of these was a request by the Birmingham Corporation for the Society to take up the direction and supervision of a series of demonstration plots for which it was prepared to provide the ground and the labour if the Society would provide the seeds of the plants to be grown, and generally direct their sowing and cultivation on similar lines to those adopted by the Society in its own gardens. The object of the Corporation in providing these demonstration plots is that their allotment holders may work more intelligently and be better informed as to the varieties which are most likely to bring about the best results in their neighbourhood. The Council viewed the proposal favourably, and plots have now been set up and the work is in progress. The Manchester Corporation are now taking similar steps, and have asked the Society to identify itself with them on similar lines.

With the view of further encouraging and extending the general range of horticultural knowledge throughout the country, not only amongst working and professional gardeners, but also amongst horticultural instructors and teachers of all grades, the Society's Examinations have been considerably revised in the direction of making them a more practical test of horticultural knowledge and experience. A Board of Examiners has been set up, which first dealt with the syllabus and regulations for both the General, and School Teachers' Examinations, so that not only has their standard been raised, but the practical experience and knowledge required of candidates in future will be increased. The School Teachers' Examination particularly has been revised, and now consists of both an Elementary and an Honours Examination, in both of which evidence of actual practical work will be required of all candidates. In the Honours section practical work will form an actual part of the examination itself.

The Degrees in Horticulture of the University of London have now come into operation, inasmuch as five candidates have entered for the Bachelor's Degree this year.

Representations have been made to the Prime Minister on the subject of Afforestation; to the Minister of National Service on Man-power and its Application to Gardeners; to the Controller of Mines on the Provision of Fuel for Horticultural Purposes, which resulted in special consideration being given in the case of valuable stocks of plants; to the Rt. Hon. R. E. Prothero concerning Seed Potatos; and to the Commission on the proposed Luxury Tax on the Exemption of Scientific and Educational Books from Taxation.

The President and Council greatly regret the unavoidable delay which has attended the publication of the Society's *Journal* during the past year—delay due entirely to the threefold cause of (1) depletion of staff, (2) extreme shortage of paper, and (3) the difficulties which have attended the printing trade all over the country. It is confidently hoped that the present year may see a great improvement in all of these respects and a consequent resumption of the *Journal's* regular publication.

Negotiations with the Government are now in progress as to the possibility of the Society receiving discharged soldiers at the Wisley Gardens for training in horticulture.

There being only one vacancy in the roll of the Victoria Medal of Honour, the Council have had very great pleasure in nominating Sir Frank Crisp, Bart.,

The Lawrence Medal for 1918 the Council have awarded to Messrs. Sutton and Sons for the excellent quality and great educational value of their frequent and really wonderful exhibits of summer-sown vegetables.

The following table shows the Society's position with regard to numerical strength during the past year:—

	No.	£	s.	d.

W. WILKS, *Secretary*.

ROYAL GARDENERS' ORPHAN FUND.

February 6.—The annual general meeting of the subscribers to the Royal Gardeners' Orphan Fund was held on the 6th inst., at Simpson's Restaurant, Strand.

Only a very few persons were present. The Chairman, Mr. H. B. May, presided. After the minutes of the last annual meeting had been read, the Chairman submitted the report of the Executive Committee on the work of the institution for the year ending December 31, 1918, from which we give the following extracts:—

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

In presenting the thirty-first Annual Report to the supporters of the Royal Gardeners' Orphan Fund, the Committee is glad to be able to place before them a statement of accounts which, while showing a smaller total revenue than was obtained in the previous year, yet indicates that the Fund has held its own exceedingly well under the very trying conditions which obtained during the last year of the war. The indebtedness to the Bankers has been increased by £150, and the Committee will be most thankful for any help towards liquidating this debt.

At the commencement of the year 117 children were receiving the full benefits of the Fund, and fourteen—a smaller number than for some years previously—were added to the list at the annual meeting. The amount disbursed in allowances and grants-in-aid was £37 less than in the previous year, eleven children having ceased to receive allowances during the year. For the coming annual meeting there is again only a small list of candidates for election, but your Committee anticipates a considerable increase in the near future.

Early in February your treasurer received the following most gratifying communication from the Right Hon. Sir Thomas Mackenzie, High Commissioner for New Zealand: "I have read with much interest the printed notice regarding the work of the Royal Gardeners' Orphan Fund, and the cases to be considered at the annual meeting. I note that certain of the candidates—11 and 12, for instance—are in especially distressing circumstances, and I therefore have much pleasure in enclosing herewith a cheque for £100 as a donation towards the Fund. This sum is a portion of an amount sent to my care from the Gore Fund, New Zealand, for the relief of British distress." A benevolent supporter—Mrs. Ward—voluntarily gave an undertaking to pay the sum of £13 per annum in support of the boy, Victor Robinson, so long as he is entitled to receive the benefits of the Fund.

Your Committee desires again to tender its grateful thanks to Messrs. Hurst and Son for their handsome gift of £100, and most cordially expresses its gratitude to Sir Frank Crisp, Bart., Messrs. Sutton and Sons, Mr. Roland R. Robbins, J.P., Mr. Whitpaine Nutting, Mr Tom Smith, and others, for substantial financial help.

The Committee has received with great regret the resignation of Mr. T. Neve, the honorary local secretary for the Reading district, on his leaving Sindlesham House Gardens, Wokingham. Your Committee desire to place on record its high appreciation of his long and valuable services. Mr. A. H. Tucker, 44, New Road, Reading, has kindly undertaken to carry on the office vacated by Mr. Neve.

Your Committee much regrets that, owing to the shortage of paper and labour and the increased cost of both, it does not consider it advisable to issue a list of the subscribers to the Fund in 1919.

THE ROYAL GARDENERS' ORPHAN FUND.

PETER R. BARR,
W. A. BILNEY,
Auditors.

January 21, 1919.

Commenting on the report Mr. May referred to the loss of income sustained by the Fund through various causes, and especially the withholding of the annual festival dinners, from which the Fund, in normal times, derived a great part of its income. They had been compelled to incur an overdraft from their bankers for a very considerable sum, and he appealed for support to make good this indebtedness. Their good work had been recognised by the High Commissioner for New Zealand, the Rt. Hon. Sir Thomas Mackenzie, who had given them the sum of £100 from the Gore Fund, raised by his countrymen.

The Committee had endeavoured to work the Fund at a minimum of expense, and, as a matter of economy, it was decided not to print the list of subscribers as usual last year, as printing was a very expensive item in these days. In conclusion, Mr. May referred to the loss by death of several strong supporters of the charity, and appealed for others to come forward to take their places.

Mr. McKerchar seconded the adoption of the report, which was carried without further comment.

The officers and committee were all re-elected, and Mr. G. F. Tinley was appointed to a vacancy on the committee caused by the death of Mr. R. Hooper Pearson. Eleven orphans were submitted by the Executive Committee for election by resolution, and as no poll was necessary, the meeting, on the proposition of the Chairman, seconded by Mr. Curtis, placed the whole of the eleven on the funds. Their names are as follows:—Frances Goldstraw, Ellen Higson Goldstraw, John Lankester, Terence William Nichols, Thomas W. Nichols, Elizabeth Ewart Pritchard, Mary Nicholson Pritchard, Livingstone Shand Reid, Isaac Bayley Balfour Smith, Charlotte Sangster Souness, John Souness.

CROPS AND STOCK ON THE HOME FARM.

THE AGRICULTURAL POSITION.

THE Crop Reporters of the Board of Agriculture, in reporting on the agricultural position on February 1, state that the continual rains, followed by frost at the end of the month, hindered field work much during January. Fair progress was made on light land, and the last few days of the month gave opportunity for carting manure in some districts, but otherwise work is distinctly behindhand. Wheat appears to have suffered somewhat on very heavy or wet land, but is elsewhere satisfactory; autumn-sown Oats and Beans seem to be good, strong plants almost everywhere.

The condition of ewes is reported as fair to good, the wet weather having proved trying. Lambing prospects are considered fairly satisfactory on the whole. The Dorset Horn flocks have practically finished lambing; the fall of lambs is reported as moderate, and the mortality light.

Live stock are generally in fair condition. In most parts of the country, but not all, the supply of winter keep is rather short.

The steady demobilisation of agricultural labourers from the Army is relieving the scarcity of farm hands, and in several parts of the country the supply has been nearly, if not quite, sufficient for the requirements of a wet month. Skilled labour is, however, still scarce. Owing to the lateness of the season, and the deficiency of labour, proper cultivation in the autumn was frequently neglected, and it is expected that the preparation of the land for the spring crops will require more labour than usual.

TRADE NOTES.

JAPANESE LILY BULBS

MR. CHAS. H. CURTIS, as secretary to the Japanese Bulb Import Control Committee, writes: "Those who wish to share in the supplies of Lily bulbs under the recent concession, allowing an importation of 10,000 cases, should apply not later than February 28, 1919, to those importers from whom they obtained bulbs in 1915-16. It is anticipated, however, that only a small proportion of this quantity will be available, and at an enhanced price, owing to the lateness of the season, enormously high freights, lack of shipping facilities, and the uncertainty of the condition of the bulbs on arrival. A copy of the Regulations supplied to importers may be seen at the offices of the British Florists' Federation, 35, Wellington Street, Covent Garden, W.C."

A SPECIAL Sub-Committee appointed by the Chamber of Horticulture has had under consideration the American Nursery Stock Plant and Seed Quarantine No. 37, which is ordered to be effective on and after June 1, 1919. Acting under the instructions of this Committee, the Government and the Foreign Consulates have been communicated with and interviewed. The result is that steps are now being taken to secure a revision of the Quarantine regulations. All exporters of nursery stocks and bulbs covered by the Order, who have not already done so, are urged to send to the Secretary of the Chamber of Horticulture, Norfolk House, Norfolk Street, Strand, W.C. 2, in confidence, figures giving (a) the total annual turnover of their American export trade, and (b) the value of stocks which have to be kept on hand in order to meet American requirements.

AT the next committee meeting of the Chamber of Horticulture the following important matters are down for discussion: (1) Labour Conditions, (2) Regulation of Imports, (3) Protection of New Varieties. The views of existing Associations connected with the trade or others interested therein are cordially invited by the Committee, and any letters on the subject should be sent to the Secretary, Norfolk House, Norfolk Street, Strand, on or before Monday next.

Obituary.

Edward Cox.—We learn with deep regret of the death, on the 5th inst., of Mr. Edward Cox, aged 81 years. Mr. Cox was for many years foreman at Messrs. Smith's Nurseries, Worcester, in the Rose and fruit tree department. He afterwards started business as a nurseryman on his own account, being joined by two of his sons, and he maintained his interest in the business until the end. His ability as a first-class propagator of fruit trees and Roses was well known to a very large number of Messrs. Smith's customers, both trade and retail, especially those who were in the habit of visiting the nurseries to select their trees. He was a man of high integrity and kindly nature.

ANSWERS TO CORRESPONDENTS.

AGROSTIS NEBULOSA: *W. and E. B.* Agrostis nebulosa is one of the most elegant of ornamental grasses, and its spikes are peculiarly suitable for association with cut flowers. If the inflorescences are cut just before the spikelets open, and are dried carefully, they will provide useful material for winter decorations. Agrostis nebulosa is hardy, and seeds may be sown out-of-doors in spring or autumn, but it is a common practice in private gardens to raise seedlings in gentle heat, or in a frame, and plant them out about 6 inches apart in April or early May. If this grass is to be grown in quantity, seeds should be sown in good soil and a warm position in early April; sow thinly in drills about 9 inches apart, and thin the seedlings lightly. If the soil is in poor condition the spikes will be short in the stem, and therefore less valuable for decorating than if 15 to 18 inches high.

CORRECTION: In the article on "Leaf Spot of Orchids," page 61, line 26, column 3, should read "3 to 4 per cent. solution of calcium bisulphite," and not bisulphate as printed.

DISEASED PEACH STEMS: *A. J. F.* The Peach growths are affected with Botrytis disease, which appears mostly on young and improperly ripened shoots. All diseased growths should be cut out, making certain that the whole of the diseased portion is removed. Spray the affected trees with a weak solution of permanganate of potash.

EFFECT OF CREOSOTED TIMBER UPON PLANTS: *J. B.* Plants in houses the wood-work of which has been treated with creosote have been known to lose their foliage as a consequence of the fumes given off by the creosote. Whether Tomatos would suffer if grown against a creosoted fence out-of-doors we cannot say, but if the wood has been treated quite recently we should regard such planting as a very risky proceeding. A few years ago, in two different localities, we saw large numbers of tuberous Begonias defoliated and quite spoilt owing to their close proximity to newly-made roads in which creosoted or similarly treated wood blocks were used. There was no other reason for this disaster, as the Begonias had been grown successfully on the same sites in previous years. Hard-leaved plants may not suffer much, but soft-leaved plants do appear to suffer considerably.

FORESTRY TRAINING: *K. L. S.* Your best course is to obtain a post as assistant on any well-wooded property and under a good, practical forester. Write to W. Michie, Esq., Woods Manager, Woodhouse Hall, Welbeck; the Woods Manager, Woburn, Beds; or one of the big Scotch estates, such as Drummond Castle, Durris, or the Seafield, applying to the Head Forester, with whom terms could probably be arranged.

GOOSEBERRY CATERPILLAR: *C. P. B.* Spraying will not prevent sawfly larvae from appearing on Gooseberry bushes, but they are readily killed if the bushes are sprayed when the pests are first seen. The best wash to use is made by dissolving 6 oz. of arsenate of lead paste in 10 gallons of water. This wash is poisonous, and should be applied at least a month before the fruit is to be eaten; non-poisonous washes are of no use. Unfortunately is often happens that the fruit is too far advanced for spraying to be done. When the larvae first appear they are congregated in colonies, and may easily be picked off by hand if the bushes are not too numerous. To clear Gooseberry bushes, Peach, Apricot, and Cherry trees of mossy growth, spray them now with lime-sulphur wash, bought in concentrated liquid form and diluted according to the maker's directions for winter spraying. This must be done before the trees start into growth.

NAMES OF PLANTS: *A. P.* 1, Cypripedium Dicksonianum (Hera × villosum); 2, C. rubescens (Boxallii × oenanthum).

PLOUGHING CLOSE TO APPLE TREES: *M. B.* If the Apples are on the free stock no harm will follow ploughing quite close to the tree stems, but if they are on the Paradise stock ploughing should not be done so closely as you suggest, because surface roots would be damaged. A space of 3 feet to 4 feet on each side of the trees should be left for hand cultivation.

SCALE INSECTS ON PEAR TREE: *J. J. T.* The common Mussel Scale (now known as Lepidosaphes ulmi), so frequently found on Apple and Pear trees, varies in shape, and the rounder form is generally designated Oyster Scale. The ordinary winter wash will not effect a general clearance of this pest, but a winter spraying with paraffin emulsion and Woburn Winter Wash has been found effective.

SWEDES FOR SEEDING: *H. S.* If the seed sown was from a first-rate stock the resulting crop of seed should be good so far as type and strain are concerned. The seedlings submitted are of excellent size and strength for the time of year. Thin them to one foot apart directly weather permits, and plant the surplus seedlings a foot apart in rows 20 inches asunder if hand cultivation is to follow, but 2 feet 3 inches apart if under horse cultivation. The seedlings which remain where sown should produce a heavier crop of seed than those transplanted.

Hyacinths, Roman, 12's, per doz. bun.	2 6– 4 0	Violets, single, per doz. bun. ...	6 0–10 0

REMARKS.—Supplies of cut flowers this morning were considerably shortened owing to the severe weather, and a rise in prices may be expected, especially for white flowers. Daffodils are arriving in excellent condition; the varieties offered are Emperor, Golden Spur, Henry Irving, Princeps, and obvalaris. Pheasant-eyed Narcissus is sufficient for the demand. Richmond is the leading variety in Roses, and soon sells at high prices. A large supply of white Lilac has arrived from Holland during the past fortnight, also a few white and coloured Tulips. The supplies from the Channel Islands have been greatly reduced during the past week, and the supplies from this quarter are likely to be limited for some time. The whole consignment of French flowers which arrived this morning were frostbitten and unfit for immediate use. Paper-white Narcissus rose to 30s. per pad of 48 bunches on Saturday. Large portion of last week's arrival consisted of Acacia (Mimosa). Several pads of double white Stocks were received last week in good condition, and sold quickly. Anemones and Violets are more plentiful.

Vegetables: Average Wholesale Prices.

Greens, per bag ...	2 6– 3 0	Turnips, per bag ...	5 0– 6 0
		Watercress, per doz	1 0– 1 3

REMARKS.—Supplies of black Grapes are now decreasing, but fairly large supplies of Almerias (Spanish) are on offer. Californian Pears now available consist of Winter Nelis and Easter Beurré, the former packed in boxes containing 165 to 210 fruits, the latter 8 to 10 dozen. Californian Seedless Oranges are on offer, and also some fine fruits of Pines (St. Michael's). A consignment of Teneriffe Tomatos is due. Forced vegetables continue very limited in supply. *E. H. R., Covent Garden Market, February 12, 1919.*

Continued from page iii.

FOREMAN; thoroughly experienced, for Fruit and Plant Houses; must be specially good on Carnations, Cinerarias, and Chrysanthemums. State wages; good Bothy and vegetables; 1 o'clock Saturdays; overtime paid.—T. SIMPSON, The Gardens, Newstead Abbey, Notts.

WANTED, FOREMEN, Inside and Outside); JOURNEYMEN, Inside and Outside; English and Scotch establishments.—STEWART & CO., 13, South Street, Andrew Street, Edinburgh.

FOREMAN required for Glass Department; 25-30; single; Bothy, coal, and light. State wages required.—W. BURGESS, Whitney, Herefordshire.

WANTED, FOREMAN, for Fruit and Plant Houses. Also JOURNEYMAN. State experience, wages required, with Bothy and vegetables.—C. JENNINGS, Littlegreen, Petersfield, Hants.

WANTED, FOREMAN and JOURNEYMAN for the Houses. State age, experience, and wages, with Bothy, &c. — J. T. SHANN, Betteshanger Park Gardens, Eastry, Kent.

WANTED, JOURNEYMAN, with good experience, to take charge (under Head) of small range of Glass, chiefly Plants; good at Carnations; duty and overtime paid; 1 o'clock Saturdays. State wages, with Bothy, milk, and vegetables.—C. RUSE, Folly Farm Gardens, Sulhamstead, near Reading.

WANTED, experienced JOURNEYMAN, for Fruit and Plant Houses, to take charge. Also strong YOUTH for Outside; take duty; comfortable Bothy and attendance; overtime paid; 1 p.m. Saturdays. —Apply, stating experience and wages, HEAD GARDENER, Brockhampton Park, Andoversford, Glos.

WANTED, JOURNEYMAN, for Fruit and Plant Houses; wages 30s.; 1 o'clock Saturdays; 3s. for duty. State experience.—M. CROOKE, Kidbrooke Park Gardens, Forest Row, Sussex.

WANTED, JOURNEYMEN, for Pleasure Grounds, also Kitchen Garden; wages 35s. to 40s., including bonus, Bothy. — State experience to W. ANDERSON, Close House Gardens, Wylam-on-Tyne.

WANTED, Two JOURNEYMEN; Inside, First and Second, experienced in Fruit and Plant Growing; discharged men preferred; state particulars of experience and wages required; Bothy and attendance provided. to GEO. GURNEY, Bodnant Gardens, Taly-Cafn.

JOURNEYMEN. —Two required as FIRST and SECOND, for Fruit and Plant Houses; wages 28s. and 24s. respectively, with Bothy, milk, and vegetables.—Apply, with testimonials, to THE AGENT, Estate Office, Lavington Park, Petworth, Sussex.

WANTED, two JOURNEYMEN; one to take charge of House, one for Fruit Trees, Roses, &c.; under Foreman.—Write, stating experience, wages required, Bothy, vegetables, and attendance (1 o'clock Saturdays), to H. NAYLOR, Pleasaunce Gardens, Overstrand, Cromer.

WANTED, two JOURNEYMEN; one for the Houses, one for Pleasure Grounds. State age, particulars of experience, wages required; Bothy and attendance provided.—T. WARRINGTON, Foliejon Park, Windsor, Berks.

WANTED two JOURNEYMEN, for Fruit and Plant Houses.—Apply stating experience, wages required, with Bothy, &c., WINTER, Grove Gardens, Stanmore.

JOURNEYMEN; Inside; experienced.—W. HUNTER, Strathfieldsaye Gardens, Mortimer, Berks.

WANTED, experienced young MAN, single; Inside and Out; lodgings found near Gardens. State wages.—C. LUXFORD, Walmsgate Gardens, Louth, Lincs.

WANTED, at once, Two good IMPROVERS, for Lawns and Kitchen Garden; wages £1 per week and Bothy.—Apply, E. STUBBINS, Lyburn Park Gardens, Lyndhurst, Hants.

WANTED, Two IMPROVERS, one for Fruit and Plant Houses, the other for Inside and Out. State experience and wages expected, with Bothy and vegetables; 12 o'clock Saturdays. — Apply, A. H. CASEY, Huntroyde Gardens, Padiham, Lancs.

WANTED, LADY GARDENER; trained, Inside, Outside; work with ladies; live in. — Apply, stating references, experience, MISS HASELL, Dacre Lodge, Penrith.

MONMOUTHSHIRE EDUCATION COMMITTEE.

WANTED, two qualified and competent INSTRUCTORS in School Gardening and Horticulture for the above county. One of the vacancies to be filled by a qualified WOMAN. State salary required and experience. Copies of two testimonials to accompany application.

THOMAS G. JAMES,
Director of Elementary Education.

County Hall, Newport.

BRITISH GARDENERS' ASSOCIATION.
(Reg. No. 1666 T.)

THE B.G.A. has adopted a new standard of wages and hours, and employers and employees may obtain a copy by sending stamped foolscap envelope to the General Secretary. Before accepting fresh situations, demobilised men are advised to write the General Secretary, B.G.A., 22, Buckingham Street, Strand, W.C. 2. Journeymen are required for good situations. Send full particulars of past experience.

WORKING HEAD GARDENER required for Cockley Cley Hall (4 miles from Swaffham, Norfolk), where four other men are kept; must have first-class testimonials as to character and ability, and be capable of producing a succession of Flowers, Fruit, and Vegetables, both out-of-doors and under Glass, and of discharging all other duties of a first-class Working Head Gardener, must also be competent to take charge of the water (hydraulic ram) and petrol gas supplies; if with one or two grown-up sons work could probably be arranged for them. Apply, in first case by letter, stating wages required, and full particulars, including number in family, to MR. J. A. ALLEN, Messrs. Chas. Knight & Co., Ltd., 227-239, Tooley Street, London, S.E. 1.

HEAD WORKING GARDENER required; well up in all branches; Scotchman preferred; five or six men kept.—Apply, giving full particulars, to THE ESTATE OFFICE, Oulton Park, Tarporley, Cheshire.

WANTED, a HEAD WORKING GARDENER of two; must be thoroughly experienced and able to take all responsibility of a gentleman's small country place.—Reply, stating age, wages, and references, to E. LLOYD, North Hall, Basingstoke.

GARDENER, good, active HEAD WORKING or SINGLE-HANDED, wanted; permanency; thoroughly understands Flowers and Vegetables; no Glass; state age, number in family, wages in last situation; reason for leaving; good five-roomed lodge and garden.—M. ROBB, Chiltley Place, Liphook.

CAN any lady or gentleman recommend an experienced HEAD WORKING GARDENER; two Under kept; must understand Vines, Peaches, Carnations, and Orchids; good wages and cottage. State age, experience, and wages required.—Apply, MRS. SELBY LOWNDES, Shenley Park, Bletchley.

GARDENER (SINGLE-HANDED) required for institution, North London; experienced in Kitchen Garden; cottage (accommodation for small family); wife might be employed in house or laundry; good references essential.—Apply by letter, stating age, wages required, and particulars of experience, to MRS. PYKE, 10, Westbourne Terrace, London, W. 2.

GARDENER wanted;—Single-handed at first, but expect enlarging Garden soon; Flower and Kitchen Gardens and some Glass; man from North or Midlands preferred. State age, experience, if married number of children, and wages required.—MAJOR W. WILSON, Horsley Gate, Holmesfield, Sheffield.

WANTED, SINGLE-HANDED GARDENER, for Garden, 1½ acres. — Apply, stating wages and previous experience, to KILROY, Omard, Harrow Weald, Middlesex.

GARDENER (SINGLE-HANDED) wanted; not much Glass; comfortable place; rooms provided.—Apply to E. H. NORTHFIELD, Grasmere, 75, Palmerston Road, Bowes Park, N. 22.

GARDENER (married), good SINGLE-HANDED, required for Lannock Manor, Weston; good wages, with excellent cottage and garden.—Apply, R. CROCKFORD, The Gardens, Weston Park, Stevenage, Herts.

WANTED, a good SINGLE-HANDED GARDENER; excellent cottage; lad kept.—POWELL, Harmer Green, Welwyn, Herts.

WANTED, GARDENER (SINGLE-HANDED), handy man; married (no family); wife as cook or house-parlourmaid.—Write, wages, references, MAJOR E. FEILDEN, The Mirrie, Denham, Bucks.

WANTED, good Carnation GROWER; also JOURNEYMAN and IMPROVER; for Fruit and Plant Houses; and a smart BOY for Gardens; good wages and Bothy.—Apply, HEAD GARDENER, Nostell Priory, Wakefield.

GARDENER wanted; married man; thoroughly experienced in Herbaceous and Hardy Plants, Lawns, &c.; wages 32s. to 35s.; cottage and garden found.—Apply, with references and experience, to HEAD GARDENER, Wittington, Marlow.

GARDENER required for gentleman's country house; must be man with good experience. —Apply, stating age, experience, and salary required, to M. H., Box 13, 41, Wellington Street, Covent Garden, W.C. 2.

NEW SEEDLING APPLE, ST. CECILIA

R.H.S. Award of Merit, Jan. 15, 1918. *R.H.S. First Class Certificate, Jan. 28, 1919.*

MESSRS. J. BASHAM & SONS have decided to distribute stock of their seedling apple, St. Cecilia, in autumn, 1919. This is one of the very best dessert apples that has been offered for many years. The trees are of robust and sturdy growth, a regular and heavy bearer, and the fruit is of brilliant crimson colour, medium size, and of excellent quality; season, January and February.

Strong Maidens, 10/6; 2 year trees, 21/-; and a limited number of 4 year, 30/- each, all on paradise.

The "Gardeners' Chronicle," February 2, 1918, says:—

The new dessert Apple, St. Cecilia, was raised from Cox's Orange Pippin crossed with an unknown variety. The seedling has much of the excellent quality of the Cox's Orange Pippin parent, and is a dessert Apple of first-rate quality, keeping longer than Cox's; fruits shown at the R.H.S. Exhibition on January 15 by Messrs. John Basham & Sons were solid and juicy, without the least sign of shrivelling. To these qualities is added a strikingly handsome appearance, the fruits, though of small size, being as shapely as the best of Worcester Pearmain, and coloured a deep red all over, enhanced on the side next to the sun. The stalk is rather deeply set and somewhat slender. The illustration shows the fruits in their natural size. The variety will prove a valuable addition to late dessert Apples, and a successor to Cox's Orange Pippin.

The "Horticultural Advertiser," Feb. 5, 1919, says:—

Apple St. Cecilia (John Basham & Sons). A pretty, brilliantly-coloured Apple, just the right size for a table fruit. The quality is equal to the appearance; in fact we never tasted a better flavoured Apple at the end of January; a very promising novelty, and worthy the attention of all fruit-growers. (F. C. C.)

A REVIEW OF THE YELLOW ROSES

"WE want a Rose with the form, colour, and fragrance of Maréchal Niel, and as strong and hardy as Caroline Testout, so that it will grow and flower well out-of-doors with ordinary care."

This, or something to this effect, was the wish most commonly uttered by rosarians twenty years or so ago, with regard to yellow Roses, and the fact that a similar wish was expressed to me in the train a few days since by a well-known Rose grower, has led me to consider how far we have travelled on the road to this wished for goal.

That some progress has been made can scarcely be denied. We have, for instance, yellow Roses of various shades, some of which approach the pure, rich yellow of Maréchal Niel; even in form there has been some progress, but size and substance of the flower leave much to be desired, while we have nothing as yet with the hardiness and vigour of growth and general good behaviour in the garden of Caroline Testout, while fragrance appears as yet to be altogether wanting. It may be, therefore, that we are still a long way from the desired end, but it is never well to despair in Rose growing, and a new "break" may come when and where we least expect it.

Maréchal Niel itself is far from satisfactory as an out-of-door plant in this country, or at least in those parts of it with which I am best acquainted. Under glass we can get a good crop of flowers in spring, but in the open a few blooms on standards, usually malformed and rather late in the season, seem to be the best we can expect. As a climber, on a south wall, it may do rather better, but even there it is far from satisfactory.

As a starting point it may be convenient to consider the yellow Roses in cultivation at the end of the 19th centuary. The old double yellow Rose, which dated back to the time of Parkinson, and which he thought of great account from the variety and doubleness of its flowers, and Cloth of Gold (1843), had both been given up in despair from the difficulty experienced in inducing them to flower at all. The small-flowered Noisette, Celine Forestier (1848), was still grown to some extent, and Gloire de Dijon (1850) was popular, as with many it still is. It is, however, far from being a true yellow, having shades of pink and apricot, and though a full flower, has no pretensions to the form of Maréchal Niel. Mme. Falcot, which came a few years later (1858), marked some improvement in colour, and a standard of this Rose in full flower is still bright and pleasing, but the flowers are not large, and show little beauty of form. Rêve d'Or (1869), another Noisette, is one of the best of the group because of its lovely foliage, good growth, and freedom of flower. Its colour, though variable, is a buff-yellow, often with a tinge of apricot, and it is a wonderful autumn flowerer. It requires wall protection, however, to give its best, and considerable attention in pruning and training.

Mme. Bérard (1870) was a Dijon Tea, and slightly deeper in colour and better in form than the type, as also was Bouquet d'Or (1872), another buff-yellow Rose. Two dwarf Tea Roses also may be mentioned as among the first of the bedding Teas, Marie van Houtte (1871), lemon-yellow with a pink edge to the petal, and Anna Olivier, a very pale buff-yellow, but somewhat deeper when grown under glass. Perle des Jardins (1874) was a distinct advance, the colour often being a deep canary-yellow, but the flower is lacking in form and distinction. Wm. Allen Richardson (1878) is a fine, deep orange with small flowers freely produced; Gustave Régis (1890), nankeen-yellow, is beautiful in the bud and a good grower, but the flower is thin. Mme. Ravary, which appeared in the last year of the century (1899), is in many respects the most satisfactory yellow Rose that had then appeared. Its habit of growth is short, stocky, and yet vigorous, and it has a good constitution, which makes it a satisfactory garden Rose. The form of the flowers also shows considerable improvement, and the colour in early summer is a good apricot-yellow. The autumn flowers, however, become increasingly poor in colour as the season progresses, and at its best the colour is far from the pure golden-yellow of Maréchal Niel.

It will be noticed that down to this period the yellow Roses were, with a few exceptions, drawn from the Noisettes and Dijon Teas. The first year of the new century, however, gave us an entirely new departure in yellow Roses. This was obtained by M. Pernet-Ducher, who sought to introduce the strain of the old double Persian Yellow, the origin of which is lost in antiquity, among our garden Roses. The first of the new break was Soleil d'Or, obtained from Persian yellow and Antoine Ducher, and the colour was certainly striking. The plant, however, was scarcely satisfactory in the garden, showing many of the characteristics of the well-known Austrian Yellow and Austrian Copper. It was difficult to manage; it seemed to resent pruning, and yet if left to itself soon became leggy and unsightly, and the branches would not infrequently die back in the winter. It was not very free flowering, and the flowers themselves were of a somewhat primitive type and of little beauty of form; but, defective as it was, it held the promise of better things in store.

The same year (1900) appeared Sulphurea, another bedding Tea. This Rose has most beautiful bronzed foliage, which sets off its sulphur-yellow flowers well. These are good early, and again in autumn, the summer flowers being generally less valuable. The blooms are very thin, with no great number of petals, and best in the bud state. Still, it is a good garden Rose and a useful bedder, though the individual flowers are not long-lived.

Lady Roberts, which appeared in 1902, is a coppery-orange sport from Anna Olivier, and a useful bedding Tea Rose, with good foliage. The deep orange colour is very variable, but at its best is very fine, and the Rose, of the decorative type, is one of the best. Its fine orange colouring seems to come particularly well in the hands of the raiser, Mr. Frank Cant, which may indicate that it responds readily to liberal cultivation. Souvenir de Pierre Notting (also 1902) is, when at its best, a beautiful exhibition Tea Rose, and the plant is a good grower, but the outside petals are so rough, and the flower so easily spoilt by rain, that it has proved a disappointment in most gardens. Passing over Joseph Hill (1903) as containing too much salmon-pink for our purpose, and Le Progrès (1904), a useful decorative Rose in its day but of little beauty of form, I come to Mme. Mélanie Soupert (1905), one of the most beautiful and refined in form of any of the full Roses we have. It was an especial favourite of the late Mr. Edward Mawley, and has the distinction, which is, I think unique, of being described in the N.R.S. Rose Catalogue as "one of the most beautiful of all Roses." It is, moreover, of good constitution, and useful alike as a bedding Rose, for exhibition, or decorative treatment. Its defects are that from an exhibitor's standpoint its petals are rather easily bruised during transit, and that the colour of its later blossoms is not so good as that of the early ones. Like many yellow Roses, the colour seems to gradually fade out as the season advances. One might almost have thought here was the Rose all have been seeking for, but it is not so, for the colour of Mme. Mélanie Soupert is far from the pure golden-yellow desired. The colour is difficult to describe, as may be seen from the N.R.S. description, "pale sunset-yellow suffused amethyst!" When one knows the flower one can perhaps see all this in it, but a stranger to it would, I fancy, hardly recognise it, and would rather conjure up in his mind something of the rainbow hues we find in Beauté Inconstante, and to such a one I would rather class it as a buff-yellow with a brighter or glowing centre. We owe this Rose also to M. Pernet Ducher.

Instituteur Sirdey was of the same year (1905), and may perhaps be described as a deeper coloured and stronger-growing Le Progrès. I once planted a bed of Mme. Ravary, Le Progrès and Instituteur Sirdey, intending yearly to weed out and replace the less satisfactory plants, and within a few years Mme. Ravary had the bed to itself. As in Le Progrès, the flowers are lacking in form.

The next year, 1906, produced two Roses quite remarkable for their deep orange-yellow. Lena is a little decorative Tea, of pretty shape and extremely useful for a button-hole flower, and worth growing for this purpose alone, but the growth and constitution are not good enough for a first-class garden Rose. The other is Marquise de Sinéty, golden-yellow, shaded copper. This also has proved somewhat difficult as a garden plant; for a time the growth is usually good, but the plants seem short-lived, and to require frequent renewal or re-budding.

Harry Kirk (1907) was classed as a Tea, a distinction it scarcely merits. The flower is of fair form and a bright sulphur-yellow, but (*pace* the R.H.S., which has included it in a list of mildew-proof Roses) it is one of the Roses most susceptible to mildew in the garden, otherwise both foliage and growth are vigorous and good. Other yellows of this year were James Coey, pretty in early summer, and Mrs. Aaron Ward, a Rose at one time highly popular in America. The flower is of the decorative type, of fair form, Indian-yellow in colour, paling to white at the edge of the petals. It is a nice little Rose, and tolerably free from disease, but I think without much distinction as a flower.

Mrs. A. R. Waddell, reddish or coppery-yellow, is a nicely-formed decorative Rose, with good growth and very pronounced thorns on the stems. The colour is particularly striking in plants grown under glass. *White Rose.*

(*To be concluded.*)

JANKAEA HELDREICHII.

The charming plant illustrated in fig. 31 has been introduced into this country several times, but few growers have been successful with it, and now it is extremely rare, probably not existing in half-a-dozen gardens. Some fine examples have been shown at meetings of the Royal Horticultural Society by Sir Everard Hambro. Among other places, it was also successfully cultivated and well flowered by Mr. T. H. Burroughes at Ketton some twenty years ago. At Kew a plant was kept in a cold frame for some years, but it could never be increased, and it eventually died. The species is said to be very rare in its native home on Mount Olympus, in Thessaly, where it grows at an elevation of from 4,500 to 8,000 feet. Like the well-known Pyrenean Ramondia in habit, the upper side of the leaf is covered with white, silky hairs, while the under-side is covered with a thick brown felt. The rosettes of leaves are about 3 inches across, and the deep blue flowers are borne two or three together on stems 2-3 inches high during the summer months. With the coming of peaceful times there is a possibility of further importations of this desirable plant, when efforts may be more successful in establishing it in rock-gardens, especially in those gardens that are not within the smoky fog radius. *W. I.*

Fig. 31 Jankaea Heldreichii: flowers deep blue.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM EVERSHOTENSE.

Eustace F. Clark, Esq., Evershot, Dorsetshire, sends a pretty first flower of a very small plant raised between Odontoglossum Lawrenceanum (Rolfeae × triumphans) and O. gandavense (ardentissimum × Vuylstekeae), which was purchased as a seedling in a batch from Messrs. Sanders, at Messrs. Protheroe and Morris's Sale Rooms, some years ago. The species entering into the composition of this variety in varying degree are O. triumphans, O. Pescatorei, O. crispum, O. Harryanum, and O. luteo-purpureum. Features which readily present themselves in the flower suggest O. Wilckeanum albens in the form of the slightly incurved sepals and petals; O. ardentissimum in the colouring, and O. triumphans in the crest of the lip and its shape. It is a pretty and distinct flower which may develop satisfactorily on a strong plant. The ground is white, uniformly blotched with mauve, the blotches being divided by irregular white bands. The lip is white, closely spotted with dark mauve and fringed at the margin. This Orchid was raised in Messrs. Sanders' nursery at Bruges.

THE SELECTION AND PROPAGATION OF PARADISE STOCKS.

(*Continued from page 72.*)

Of Paradise stocks which are undoubtedly of inferior character, are those of Type 3 (possibly Dutch Doucin, nick named by us "Holly-leaved," which has an evil habit of suckering badly at the collar, whilst it is very liable to Black Spot and Mildew on the leaves and shoots, and appears quickly to deteriorate. Type 8, the French Paradise, cankers and scabs badly on our soil, and in a few years the stools deteriorate, and even die out altogether.

At the present time, then, it would appear safe to recommend commercial fruit growers to ask for their bush trees preferably upon Broad-leaved, Doucin, or Nonsuch Paradise stocks. I think they may reasonably expect a rather more vigorous tree, and therefore possibly less early maturing upon the Broad-leaved. If these three stocks are unavailable, then our Type 7 appears to be quite a desirable stock, somewhat similar to the Doucin, but less coarse and feathered. If the grower is looking for a tree of less permanent nature to be used as a "filler," one would feel inclined to recommend either Type 5, the Improved Doucin, or the still more dwarf Type 4, Malus pumila.

From the nurseryman's point of view, undoubtedly the Broad-leaved and the Improved Doucin are the most easily propagated types which produce a stock of a quality altogether desirable for budding or grafting. Such, at any rate, is the six years' experience upon our soil, which may be described as a lightish loam. To sum up, our efforts have been in two directions: 1, to ensure a generally higher level of young trees for the fruit-grower, trees which may reasonably be expected to fulfil certain predictions; 2, to help to supply the nurseryman with a healthy, standard-sized stock, easy to propagate and suitable for a definite purpose.

We have made the first step in both directions with regard to Apples, and we have collected information enough to enable us to work on similar lines with other fruit tree stocks.

Whilst the full influence of the stock upon the scion is at yet imperfectly understood, one practical result at any rate is assured, i.e., a much more general uniformity in vigour and health of the young tree, an advantage both to the raiser and the grower.

Fruit tree raisers of all classes have only too often in the past relied upon "buying in" the bulk of their stocks from abroad. The raising of stocks is almost an industry in itself, and I do not suppose it will ever become a part of the business of the smaller nurseryman or of those who do not specialise in commercial fruit trees, but it is worth pointing out that, although some of the foreign nurseries have carried out this business on a larger and more accurate scale in the past than some of our own, yet they do not produce, so far as I have been able to ascertain, a single stock of two of the most valuable types of Paradise for this country, i.e., Type 1, the true Broad-leaved, or Type 6, the Nonsuch Paradise.

The bulk of the Paradise stocks from France is the true Doucin (Type 2), commonly sold on the market as "English Paradise," and very frequently wrongly as "Broad-leaved English Paradise." The other types which the French nurseries supply are the Improved Doucin (Type 5) and the Jaune de Metz Paradise (Type 9), to both of which I have already referred as possessing a value of their own for distinctly dwarfing trees. Finally, they supply the true French Paradise (Type 8), which is altogether unsuitable for this climate. From Holland, the other country to which we have looked most in the past for a supply of stocks, we receive a certain amount both of the Doucin and the Improved Doucin, and also a considerable bulk of that very distinct and dwarfing Type 4, which we have referred to as probably "Malus pumila." Both these countries need to adopt steps similar to those which our own Horticultural Trade Association is encouraging, in order to purify their stock.

Meanwhile, without raising the controversial question of these imports, our own stock raisers have a clear field for raising the true Broad-leaved Paradise, which there seems no doubt will be ever in greater demand. The wholesale destruction of trees in parts of France, the general impetus given to replanting and fresh planting, and the world-wide neglect and consequent shortage of stock beds should give us on this side of the water encouragement to increase our production of home-grown stocks as systematically and rapidly as possible during the next few years.

It is with these facts in mind that I have already summed up the general conclusions arrived at with regard to the various dwarfing Apple stocks, and that I now append for the information of those interested some details as to the results of experiments in the various methods of raising the most desirable types.

Stool Propagation.

At the outset of our experiences we resorted to planting out the stocks we received, 4 feet apart, with 6 feet between each row. We now plant them at 3 feet, with the rows 4 feet apart. These stocks were of average size for working.

but we allowed them to stand in the ground a year before heading them back for stools. Early in the second spring they were cut back to within two or three buds from the ground level, and as soon as the resulting shoots had grown out 4 or 5 inches we started earthing them up, usually early in July. This process of earthing was repeated several times during the growing season, until the stool appeared as a small mound some 6 to 12 inches high.

At the end of the growing season the mound of earth was drawn away with a fork and the stool stripped of all its shoots. We found it best to leave the stool thus uncovered until the new shoots had grown out again to 5 or 6 inches in the coming spring, then the whole process was repeated. Stools thus treated from 1912 onward are still in full bearing with us.

Certain points are worthy of notice:—

1. We started our stools slightly wider apart than necessary in the first instance in order to be able to keep separate any admixture we might find.

2. The first year or two the new stools produced fewer and coarser shoots than they are doing now. These rooted less regularly than those of medium strength, and were often too coarse for working after six months' bedding.

3. The amount of established rooting that we obtained as a result of our careful earthing up well repaid us for the labour expended. Our rooted shoots, and with most types nearly 100 per cent. rooted, compared very favourably indeed, with one- and even two-year bedded stocks from other sources.

4. We found the wood of the current year's growth much more ready to root adventitiously than hardened wood of the last year's growth.

The number of rooted shoots obtained annually varied somewhat, according to the type of Paradise, but generally it increased as the individual shoots became less coarse with the age of the stool. It would probably be fair to average the annual take per stool as 7 or 10.

Laying the Stock.

As an alternative method of stock-bed making we tried planting each stock in the first instance on the slope, so that we could lay the whole along the surface of the ground. As before, we allowed the stock to establish itself for a season before taking any layers off it. At planting the stock was lightly tipped, and the lateral shoots cut to within a bud or two of the main stem. As with the stools, we found it better to leave the stock uncovered until it had sent out shoots some few inches long. This it was induced to do all along the stem as a result of the tipping and cutting in. The whole stem was then moulded over several times in the season as before, which process we started the first year in this case, and in the course of a season or two we found the whole stem rooted in the ground. A whole series treated in this fashion affords a continuous row of stocks. This is a safe method where one is sure no rogueing will be required. From a commercial point of view, provided all the stocks are true, we recommend this laying method for several reasons:—

1. It is inclined to produce rather more shoots annually, and apparently they are more even in quality.

2. The less freely rooting types, such as Doucin, Type 4, and Type 7, appear to root distinctly more readily this way.

3. The individual stocks are straighter than those off the stools already described, where the weight of earth gives them a noticeable bend.

4. The actual earthing process is easier by this method, and could probably even be performed by the use of a strike-plough.

The Severing of Stocks from Stools.

With some varieties which root adventitiously as far as earthed up, such as Broad-leaved, Improved Doucin, and Nonsuch Paradise, we found it quite simple, either with a Hop knife or very strong secateurs to cut the rooted layers from the parent stool. But with types which root mainly towards the base, and even then somewhat shyly, we found it necessary to tear them off from the parent, often with a slight heel of old wood. It might be supposed that this drastic treatment would materially injure the stool in the coming year, but so far we have not found this to be the case, though certainly less damage is done on the laying system than to individual stools. In the former system especially it is quite easy every now and again when the row seems getting worked out to renew it by leaving here and there strongish shoots and pegging them down in the gaps.

As regards the rooting habit generally of these one-year shoots, it is nearly always the medium growths which root well and form the best quality stocks. The coarsest growths in every type root most shyly, and we make it a practice now to break out these when the season is advanced enough. On the contrary, the finest growths, the whips and feathers, are almost as shy to root, but we find these very useful in the laying system to cut in each year to two or three buds which in the following season produce several admirable stocks, which root readily. As already stated, as the stool matures the quality of the stocks appears to increase.

The Bedding of Stocks.

In many commercial nurseries which I know, little or no earth is drawn up to the stools from which are annually taken shoots of any age which appear to be of a workable size. These are often sparsely rooted or not rooted at all, and they may be regarded more or less as cuttings. They are bedded in the ground for a year, are treated as cuttings, and then transplanted into their permanent position for working. In other words, they are at least eighteen months old before they are fit for budding, and they may have been several years upon the parent stools before that.

From the point of view of quickness and labour-saving, our method of rooting well the one-year shoots on the stool saves 12 months, for we find that all the medium growths, and that is the vast majority, are fit to plant out at once as stocks, requiring no bedding, and they take the bud well in the coming summer. In the country's present shortage of stocks, surely this is a great consideration; moreover, the one- and two-year bedded stocks above described do not compare in rooting vigour with this type. We have now budded and grafted several thousand trees on stocks raised in this manner, and everyone testifies to the vigour of the maiden trees.

A small minority of the stocks raised by the methods we have described of course require bedding for a season, because they are not stout enough to work, but even then they are much better rooted than the average bedded stock. *Reginald G. Hatton, Director, South-Eastern Agricultural College, Wye, Kent.*

(*To be concluded.*)

FIG. 32.—ALLIUM KANSUENSE IN ITS NATIVE HABITAT.
(See p. 84.)

THE ALPINE GARDEN.

ALLIUM KANSUENSE.

THE dainty little blue Garlic illustrated in fig. 32 is not so hardy as several other species, but I grew it for a considerable number of years until an almost arctic winter deprived me of my bulbs. It is a small, delicate-looking plant, some 6 inches or so high, with charming, drooping blue flowers. My plants grew well in dry, sandy soil, and, but for the untoward winter, which was such as only comes once or twice in a lifetime, it would have been with me still. I have not replaced them as there have been so many others to become acquainted with. But Allium kansuense may be commended to the consideration of those who love out-of-the-way and beautiful little bulbous plants. It is, I believe, still obtainable from the trade. *S. Arnott.*

[The illustration in fig. 32 is reproduced from a photograph taken by Mr. Reginald Farrer on the Roterdspitze.—EDS.]

HERB-GROWING.

THE war has taught us many lessons. It has revealed to us the fact that we have neglected an industry and thus necessitated the importation from Germany and Austria of plants and herbs used in medicine and for cooking purposes. It is true there are to be found herb farms that are worked in connection with pharmaceutical manufactories, notably at Mitcham, Carshalton, Hitchin, Ampthill, Wisbech, and one or two other places, but these are not sufficient to meet the needs of the country. There is also a herb-growing school and nursery at Chalfont St. Peter, under the directorship of Mrs. M. Grieve.

This new industry is one that should commend itself to all lovers of outdoor occupations—allotment holders and others—and there are undoubtedly many such who could spare a few square yards of their land for the cultivation of a few herbs.

The question of soil should be considered, and to make a beginning a few of the commoner kinds grown—Parsley and Mint on a clay soil, Thyme and Sage on a chalky soil. Later, the Poppy might be grown; it is one of the plants the Board of Agriculture strongly recommended for cultivation. Its cultivation combines profit with patriotism, present prices being high, and likely to be maintained for some considerable time.

Individually, a herb-grower may not be able to do much, but it might be possible for a few holders to unite on a co-operative basis, and cultivate such herbs as may be easily disposed of in the open market, the several holders harvesting at the same time and sharing the profits.

It is therefore to be hoped that herb-growing, instead of being confined to a few, scattered here and there, will be recognised as an industry which will commend itself to many who will take up the work feeling that they are providing for the wants of the nation from both commercial and medical standpoints. *J. C. Wright.*

BULBOUS CHERVIL.

LATELY we have been rejoicing over dishes of this vegetable, and all friends who partake of it acclaim its merits, and take more than one helping. We usually serve it as an "entremet" by itself, but it would lend itself well to use as a "force" for turkey or guinea-fowl where a chestnut stuffing is appreciated. I fancy that many uses could be made of it, such as in pudding form with chocolate. We have the roots boiled whole and the skins removed afterwards, and our cook informs me that the contents "pinch" out readily, especially if the roots are kept in the hot water till they are treated, as if they are dried off the skins do not part so readily; smaller sized roots can be dealt with by the ordinary Potato-masher, in which the skins are retained by the gauze screen.

In the cultivation, the great point is to remember that when exposed in the ordinary way the seeds lose their germinating power. My first attempt to grow it was with seeds supplied in ordinary packets in the spring, which one of our leading seedsmen supplied; naturally, not a single seedling appeared. Either the seeds must be sown soon after they have ripened (e.g., in October), or they must be preserved by storage in layers with dry earth, and sown, if possible, about February; if the pot containing them is sunk in the soil and sheltered by a slate or cloche, they keep well, but are apt to commence germinating in February. On the whole, it is better to sow without storage, and keep a pot full of "stratified" seeds in case of accident. A rich soil appears to be requisite, and one may, perhaps, assume from the wants of other sugary roots that a liberal supply of potash should be forthcoming; water, too, must not be stinted in dry weather. A friend once remarked to me that he would not try growing this vegetable, as he could not supply "the sewage and sunshine of Rome."

The small, delicate seedlings, which start forming round little "tubers" whilst still in seed leaf, are rather difficult to thin, but good spacing is requisite to get roots of fair size. The ground is soon cleared for another crop, as by the end of June the Chervil may be lifted—in fact, it facilitates matters if the leaves are not allowed to die off completely ere the harvesting takes place. Owing to the early loss of germinating power, it is probably advisable to put out a few of the best roots for seed production. So far as my experience goes, slugs seem to be the only enemy, and no disease has so far appeared; as noted with Sugar Parsley, blossoms on some plants "miff off" for some reason or another, so that for seed-saving it is well to have several plants. *H. E. D.*

NOTES FROM BELGIUM.

M. LOUIS GENTIL informs us that the annual meeting of the Royal Linnean Society of Brussels was held on January 26, while the British troops were marching through the streets of Brussels. M. Jean Massart, chairman of the Royal Society of Botany, and Professor at the University of Brussels, proposed the following motion, which was unanimously passed:—"The Royal Linnean Society of Brussels, meeting together for the first time in annual meeting since the liberation of Belgium, January 26, 1919, has decided: (1) To remove from its list of members, and not admit in future, Germans, Austrians, Bulgarians, and Turks. (2) That its members shall resign from all societies of the Central Powers, and refuse to exhibit, to act as jurymen, or to take any part in any horticultural exhibition anywhere where Germans, Austrians, Bulgarians, or Turks are invited: in fact, to cease their collaboration in any enterprise where they would meet men of the Central Powers. (3) To stop the exchange of its publications with the societies of the Central Powers. (4) To engage its members to stop all individual exchange of publications or works with natives of the Central Powers. (5) The Society decides to exclude for ever those of its members who have compromised themselves with the enemy during the abhorred occupation."

Mr. Arthur De Smet, president of the Général Association of Belgian Nurserymen, and chairman of the High Council of Horticulture of Belgium, has been appointed State Counsellor for Horticulture, attached to the Board of Agriculture.

The great question of the American prohibition of the importation of plants in the U.S. is viewed with great concern by Belgian horticulturists.

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Cucumbers.—Seedlings raised as previously advised should have made good progress, and be ready to plant out on the hot-bed, which should be prepared six days previous to planting. This allows time for the bed to settle and the compost to become warm. A suitable soil at this season consists of three parts turfy loam and one of flaky leaf-soil, with a little mortar-rubble to keep the compost porous and sweet. Place it in hillocks at 3 feet apart and 8 inches in depth to receive the young plants, and just cover the whole of the hot-bed with the same compost. Plant, and stake to the bottom wire, at which position stop the leading growth; train thinly, and do not overcrop. Maintain a moist atmosphere, but water very carefully until the plants are well established. A temperature of 65° at night, rising to 85° by day, with sun-heat, will suit these young Cucumbers.

Autumn-Sown Onions.—Should the weather and the soil be favourable, seedling Onions should soon be transplanted. Lightly fork over the surface, adding a dressing of burnt garden-refuse. Rake level the surface, and plant in rows at 1 foot apart, observing the same distance from plant to plant. All spare plants should be taken from the seed-bed and planted thickly and firmly on a side border for early use. If Shallots and Garlic are not yet planted lose no time in inserting them at a foot apart each way.

Onions under Glass.—Onions sown early in the year will now need pricking off into boxes. The plants should first have developed three or four good roots; they will then be in a position to grow sturdy and strong. Use soil composed of three parts loam and one part each of sand and finely-sifted Mushroom-bed manure. Prick out at 3 inches apart, and grow on in a temperature of 50-55° for the present. Later, inure the seedlings gradually to more fresh air in readiness for April planting.

Cabbage.—The weather has been very trying for this indispensable crop. Give every aid, when possible, by frequent hoeings, with broadcast sowings of soot and wood-ashes, also fill blanks with spare plants from the seed-bed.

Turnips.—Make a sowing of Turnips on a very gentle hot-bed, in a layer of 6 inches of prepared soil. Do not unduly force the plants. Good varieties for this sowing are Long Forcing and Red and White Milan.

Potatos.—When the weather permits, stores and clamps should be examined and the tubers turned. Break off all growths, so as to retain the firmness and flavour so essential to good cooking qualities.

Red Cabbage.—Now is an excellent time to sow this crop. Sow in boxes in gentle heat, and prick off when ready into other boxes, planting out at the end of April.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Soils.—Certain land is more adapted for fruit-growing than others, and to grow fruit successfully it is necessary to have a knowledge of the composition of the soil. Manures that will suit one kind of soil are not always the best to use in other cases. A rich loam may be considered the best rooting medium for fruit trees; loams are mixtures of clay, sand and humus, the clay and sand being in small quantities. Sandy land incorporated with clay and decayed vegetable matter may be made a good fruit-growing soil. Clay soils, when drained, limed, and lightened by adding sand, are also suitable for fruit-growing. Clay soils should be turned to a good depth and exposed to the weather for a long time before making an attempt at planting. Well-drained peaty soils mixed with loam and

lime are suitable for fruit-growing. Loamy marl constitutes one of the best soils for fruit-growing, especially for Cherries and stone fruits. All marly soils are not good, as some contain an excessive amount of clay, whilst others are too porous. In almost all cases soils may be made suitable for fruit-culture provided the necessary work is done and the necessary ingredients, of which they may be short, are added.

Preparations for Grafting.—Trees intended for grafting should be headed back, but not in frosty weather. The stumps are best left a little longer than they will be when the graft is inserted, to allow of cutting down to fresh tissue. Select well-ripened shoots of last year's wood for grafts; place them in a trench under a shady wall and cover them nearly to the tips with soil till they are wanted for grafting.

Winter Treatment of Raspberries. This consists of cutting out the old canes and weak growths and, where trellis-work is used, tying the shoots about 6 inches apart. Clear away all rubbish and weeds and apply a mulching of farmyard manure about 2 inches thick. The soil about Raspberries should never be forked deeply, as this would damage the surface-roots; all that is necessary is to remove the weeds. Where farmyard manure is not available a mixture of 4 parts superphosphate, 3 parts kainit and 4 parts bone-meal, at the rate of 4 lbs. to the rod, may be given. All this work is best done in the autumn, but it may be undertaken now. All canes not required for forming arches should be shortened to 6 feet or less.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Lt.-Col. Sir G. L. Holford, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Thunia.—Although the Thunias are now referred, botanically, to the genus Phaius, they form a remarkably distinct, beautiful, and graceful group of Orchids, and I know no others of equal merit more easily grown and propagated. The plants can be grown in an ordinary plant stove, freely exposed to the light, but shaded from the fiercest rays of the sun, and where the atmosphere is kept humid. At this season of the year the plants will show signs of growth, and when the young shoots are about 2 inches long new roots are freely produced from their base, therefore repotting should take place before this stage is reached. Annual repotting is necessary, and all the old material should be shaken from the plants, while the roots, being dead, must be cut away, except a short length to help keep the bulbs firm in the new material. The pots require extra good drainage, as Thunias need a large amount of water at their roots when in full growth, and they also need only a moderate amount of soil, therefore the pots require to be filled to one-third of their depth with drainage material. The compost should consist of two-fifths peat, two-fifths fibrous loam, and one-fifth Sphagnum-moss. Use this in a rough state with plenty of coarse sand and crushed crocks added to keep it open. By using 24-sized pots four or five stems may be planted together, and to fix the plants with the greatest ease each old stem should be tied tightly to a neat stake, so that when the pot is prepared and the soil brought up to about an inch below the rim, the stakes may be fixed in the pot, just leaving the base of the stem in the soil. Water must be given somewhat sparingly at first, but as the roots begin to fill the pots and the young growths extend, more will be required. Frequent damping between the pots and occasional overhead sprayings will do much to encourage growth.

Propagation.—Strong stems will each produce two or more young growths, and provide a means of increasing the stock. Thunias will grow readily from cuttings, and the best time to take cuttings is when the plants have become firmly established and the new growths are about half grown. Then remove about half the length of each old stem, cut these into lengths of about 6 inches, and insert close to the sides of a pot filled with sand and chopped Sphagnum-moss. Place them in a warm propagating frame, and when new growths are produced, pot them singly and give the plants every attention. They will not require a long rest the first season, and it will be at least two years before such plants grow to flowering size. Where a stock of Thunias is grown a few plants should be started earlier and others kept back for a time, so as to prolong the season of flowering.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to C. H. Berners, Esq., Woolverstone Park Gardens, Ipswich.

Early Vineries.—Vines in the earliest house will now be progressing rapidly, and thinning the berries should receive early attention. This work should be carried out boldly, so that it will not be necessary to thin the bunches again. By this time all growths should be tied into position, and the laterals kept pinched back, allowing sufficient growth to extend to provide a good spread of foliage without crowding. When the berries are swelling freely, and up to the time of their ripening, lateral growth is very slight, and due account of this should be taken into consideration when shoots are being stopped in the early stages of growth. The temperature fluctuates so rapidly at this time of the year that much harm may be done in a few minutes by faulty ventilating. Maintain a humid atmosphere, but not excessively so, and aim at a night temperature of from 60° to 65°, allowing a rise of 10° during the day.

Second Early Vines.—During the flowering period afford a somewhat drier atmosphere and admit a moderate amount of fresh air, according to the climatic conditions. Black Hamburgh and Foster's Seedling Grapes require little assistance beyond a sharp tap on the Vine about mid-day, to assist fertilisation, but setting may be further assisted by lightly drawing the hand over the bunches. If not already done, all superfluous bunches should be removed to relieve the strain on the Vines. Stopping and tying down the growths must be closely attended to, and where it is desirable to lay in young rods the best placed growth near the base of the Vine should be allowed to grow on unchecked to a length of 5 to 6 feet, when it may be stopped, the ensuing growth being allowed to extend the full length of the old Vine before further stopping is required.

Late Vineries.—The necessary work preparatory to starting late Vines should be completed without delay, and the house kept close, without fire-heat, until the buds commence to burst, when a little fire-heat will be beneficial. In the colder districts it is advisable to start the latest Vines by the end of February, and a week or ten days later in more favoured parts. Referring to an old note-book I find the latest house was started about February 21, in the north-east part of Yorkshire. Grapes from this house kept up the supply until the earliest forced bunches were fit to be cut.

PLANTS UNDER GLASS.

By James Whytock, Gardener to the Duke of Buccleuch, Dalkeith Palace, Midlothian.

Zonal Pelargoniums. — Pelargoniums required for the decoration of greenhouses or conservatories in summer should be transferred to 6- or 7-inch pots, using fresh loam and leaf-mould mixed with a plant food. Place the plants in a warm house. When the pots are well filled with roots, give the latter a liberal supply of manure water. Varieties of Zonal Pelargoniums suitable for winter flowering may be propagated from cuttings inserted now and the old plants retained for planting in the open.

Climbing Plants.—The present is a suitable time to prepare climbers for the coming summer, either in a warm conservatory, a warm plant house, or a cool greenhouse. For the former structure Allamandas, Bougainvilleas, Clerodendron Thomsonae (syn. Balfouri), and Stephanotis are suitable kinds if planted in a border not exceeding 3 feet square. For slender-growing plants less space will be needed. Provide good drainage, and soil composed of fibrous loam, peat, and sand. In the case of old-established plants, remove some of the old top soil, sprinkle a little good plant fertiliser on the exposed surface, and apply a top-dressing of fresh soil. Thin out and cut back the previous season's growth. For a cool greenhouse red and white Lapagerias, Passifloras, Plumbago capensis, Swainsonias and Fuchsias are suitable subjects. Lapagerias grown in a cool house, preferable on the back wall of a house facing north, well repay careful attention. Provide a border 2 feet wide and 4 feet deep; put in 2 feet of drainage material, on this place turves of loam, and then fill in with a mixture of good loam, peat, sand and lumps of charcoal. Given these conditions Lapagerias will make strong growths, but as these are liable to be destroyed at an early stage by slugs, protection must be provided by means of sulphur, lime, or soot, or rings of zinc. Train the shoots up the back wall and along under the glass roof. If grown in pots, good drainage is equally essential for Lapagerias.

Achimenes. — Place the Achimenes tubers thickly in shallow boxes, cover them lightly with soil, and provide a temperature of 60° until they make a little growth, when the plants may be transplanted into pans or hanging baskets for conservatory decoration.

Foliage Plants. — Where it is desirable to raise a fresh stock of ornamental foliage plants, Crotons and Dracaenas may be ringed now. Roots of Dracaenas cut into small pieces, put in pans in sandy soil, and plunged in bottom heat, offer a ready means of increase. Coleus and many other plants may be propagated from cuttings at this season of the year.

THE FLOWER GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet, Hertfordshire.

Herbaceous Paeonies. — The varieties of herbaceous Paeonies are numerous, and include many with beautiful colouring and some that are sweetly scented. They should be given a good, open position, and be planted in deep, mellow loam with plenty of rotted manure added; the site should be well drained.

Paeonia Moutan.—The tree Paeonies should be given a partially sheltered position, and in severe weather a little protection should be afforded. Bracken or light strawy litter distributed amongst the branches will prove effective. Well-established plants need feeding to assist them to maintain vigour and to produce good crops of bloom; a good mulching of decayed manure, especially if the soil is light and poor, will greatly help the plants.

Summer Bedding.—If the designs for the coming season have been decided upon the stocks of plants and seeds should be examined in view of propagating. Pelargoniums and many other useful subjects will be scarce, therefore annuals may have to be employed freely. Chrysanthemums in variety, Coreopsis, Clarkias, Dianthuses, Gaillardias, Eutoca viscida, Godetias, Lavateras, Malopes, Phlox Drummondii, Poppies, Asters, Stocks, Salvias, Scabious, Tropaeolums and Antirrhinums are all useful, and may be employed for summer flowering, both in beds and borders, with good effect.

Pelargonium.—Where Pelargonium cuttings were rooted in boxes last autumn, for bedding-out purposes, now is a good time to shake them free from the old soil and pot them into 3-inch pots, in a sweet and light compost. Pot moderately firm. Place one or two plants in each pot and stand them in a warm greenhouse to encourage fresh roots. Keep the soil just moist and do not over-water. If more plants are needed allow the leading growths to elongate, and when sufficiently long cut them off and insert them as cuttings. Placed in heat these should root quickly and develop into useful plants.

Propagation of Dahlias.—Examine the stored Dahlia roots, and if the stock is to be increased put some in light soil in boxes and place them in gentle heat. As soon as the young growths are large enough, stock may be increased by cuttings or division. For cuttings the very sandy soil must not be kept too moist. Seeds of both double and single strains of Dahlias may be sown at once. If carefully attended to and given every encouragement, fine plants will be obtained by the first week in June, and these may (assuming they have been duly hardened) then be planted out on rich land.

EDITORIAL NOTICE.

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 25—
Roy. Hort. Soc. Coms. meet: Lecture by Capt. Arthur Hill, M.A., at 3 p.m., on "The Care of Our Soldiers' Graves."

SALES FOR THE ENSUING WEEK.

WEDNESDAY, FEBRUARY 26—
Sale of Rose and Fruit Trees, Herbaceous Plants, Begonias, Flower Seeds, &c., at 67/68, Cheapside, by Protheroe & Morris, at 1 o'clock.
Sale of several hundred cases of Retarded Japanese Lilies at 67/68, Cheapside, E.C. 2, by Protheroe & Morris, at 4 o'clock.

THURSDAY, FEBRUARY 27—
12,000 Fruit Trees, Apples, Pears, Plums, and Cherries, &c., at The Nurseries, Halton, near Feltham, by order of Messrs. S. Spooner & Sons, by Protheroe & Morris, at 12 o'clock.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.1°

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, February 19, 10 a.m.: Bar. 29.28; temp. 41°. Weather—Dull.

Plant Dyes. To the botanist who takes an interest in the chemical attributes of plants, no less than to the professional chemist, the publication of a full and authoritative account of the natural colouring matters of plants* is a noteworthy and welcome event.

The authors, who are well known for their researches in the chemistry of plant pigments, have produced an exhaustive work, to which the botanist may turn with the certainty of finding all that is at present known on the important and difficult subject of the chemistry of plant pigments. It is the fault not of the authors but of Nature that the chemical constitution of these substances is so complex; but in spite of the formidable formulæ which represent the constitution of flower- and other plant-pigments the serious student who has some general knowledge of chemical principles will be able to obtain probably for the first time a clear understanding of the nature and mode of formation of vegetable pigments. From the industrial point of view this work is in a sense an obituary notice which commemorates the virtues of bodies which once played a conspicuous part in the world, but which are now all but industrially defunct—having, as is the way of the world, been superseded by artificially produced substitutes.

Such is the fate which has befallen the queen of natural pigments, Tyrian purple—the dye derived from a marine mollusc, and such that of Madder, at one time the most universally used of all pigments. Natural indigo still lingers in the land of the living colours, but is fighting for its life with synthetically-produced indigo.

It is small wonder that the ancient world made use of plant dye stuff, for once the art of mordanting became known, it was soon discovered that almost every kind of plant is capable, in the presence of a mordant such as alum, of yielding a more or less valuable dye stuff—Onion skins, Alder bark, Walnut skins, fungi of various kinds, dry Heather—still used in remote districts of Scotland and Ireland—as well as hosts of plants of tropical origin have all been used, for, besides making colours for the adornment of her flowers and fruits, Nature has supplied to almost all her children of the plant world colourless or yellow chemicals known as flavones which, when used with mordants give yellow or green dyes. These colourless or faintly coloured mothers of dyes occur in the plant in combination with sugar, in the form of glucosides. When the plant tissues are destroyed the combination of sugar and potential dye is broken up, often by the agency of enzymes contained in the plant itself, and the potential dye is transformed into a gaudy colour at the chemical touch of a mordant. Thus it may be claimed for Nature that her potentiality for beauty is greater even than her actual display, lovely though that be. Known long years ago to Egyptians, Persians, and Indians, Madder is one of the most ancient and important of natural dyes. It is extracted from the root of Rubia tinctoria, which in many countries is called alizari—hence the name, alizarin of its artificial supplanter.

To the botanist the most interesting of the natural pigments are those known as anthocyans, which give the blue, purple, and red colouration to flowers. Thanks to the researches of Willstätter, Everest, and others, the chemical constitution of these pigments has now been settled beyond doubt. They are closely related chemically to the yellow or colourless flavones to which reference has already been made. The blue, for example, of the Cornflower is now known to be a potassium salt of a complex compound which in the free state has a violet colour, and the red a combination between this substance and a plant acid. In the plant the anthocyan is in the form of a glucoside, though a small amount of the uncombined, i.e., non-glucoside pigment, known now as cyanidin, may also be present.

When oxidised the cyanidin gives rise to a yellow substance which is, or closely resembles, a "flavone." Similarly, by reduction, red pigments are to be obtained from the flavones. Thus the laboratory at long last has succeeded in discovering the nature of the raw material from which these natural pigments are produced by the plant and the method whereby they give rise to pigments. Much, however, remains for the botanist to discover before it can be claimed that Nature's infinite book of secrecy may be read right through. He must be able to tell us how it is that the colours of plants are in general so stable, and how different varieties of a species contrive to breed perfectly true to a definite shade of colour. It is true that there are examples of flower colours which change as the daylight passes, but they are rare. How Nature makes constancy out of such inconstant things is the puzzle here as elsewhere.

In any case, the scientific botanists and the hybridists are deeply in the debt of the authors of this work, and will profit greatly by the labours of the authors not only in writing it but by their researches, which made possible the writing of many of its most valuable pages.

* *The Natural Organic Colouring Matters.* By H. G Perkins and A. E. Everest. Monographs on Industrial Chemistry. (Longmans, Green & Co.) 1919. 28s. net.

Coloured Plate in our Next Issue. — The issue for March 1 will contain a supplementary, full-page, coloured illustration of Odontadenia speciosa. Readers should see that this illustration accompanies each copy of the *Gardeners' Chronicle* of the above date.

Allotments in the London County Council's Parks.—It is announced that holders of allotments in the parks administered by the London County Council will have to surrender their plots on January 1, 1920.

Horticultural Degree.—At the annual meeting of the Royal Horticultural Society, held on the 11th inst., the Chairman, Sir ALBERT ROLLIT, stated that the society had been the means of linking up elementary and secondary horticultural education with scientific training at the University of London, on the Senate of which he had moved and carried the conferment of Degrees in Horticulture, which had thus been, for the first time, raised to University rank. The first examination for the Degree of Bachelor in Science for Horticulture, for which there were already five candidates, is just about to take place.

New Roses at Bagatelle.—A trial of Roses will be conducted at Bagatelle, Paris, during 1919-1920. Plants sent for trial should, so far as possible, be raised in pots, and five at least of each variety are required; they should reach Bagatelle before April 30 next. The plants will be inspected by the jury during two seasons, and the final awards made in October, 1920.

Wart Disease in the South.—According to the Parliamentary Secretary to the Board of Agriculture, wart disease was first reported among the Potato crops in Kent in 1914. Eight cases were reported in 1918—including one case in the administrative County of London. In certain districts in the North of England the planting of susceptible varieties has been prohibited, but the approved immune varieties that are allowed to be planted in these areas include some of the heaviest cropping varieties under cultivation. As regards the movement of disease from the infected areas of the North of England, under the Wart Diseases of Potatos Order of 1918 the planting of Potatos grown in an infected area is prohibited except in that or in another infected area. In several cases in-

fection has been traced to "seed" imported from Scotland, especially of the Arran Chief variety, and the Board have under consideration the issue of an Order prohibiting the movement into England and Wales of "seed" of the susceptible varieties from Scotland without due safeguards.

Allotments at Bushey Park.—The Allotments Committees of the Hampton and the Teddington District Councils are endeavouring to persuade the Office of Works to extend the tenure of the allotments in Bushey Park. Owing to the lateness of the season when the ground was available for cultivation and the prolonged bad weather at that time, the results which the holders obtained from their plots were so discouraging that, particularly as the plots have to be relinquished at the end of this year, few are inclined to work them. It was hoped that the Office of Works, in view of the need for Food Production, would be inclined to let the land for a period of five years. To this request the official reply is that the authorities are unable to vary the conditions stated in their letter of March 18 last, but the use of the ground would not be withdrawn until the crops which will shortly be planted had been secured. It was then, however, decided to make a further application to the Office of Works, and to send a copy of the correspondence to the Middlesex War Agricultural Committee, requesting support for the Council's application. In the meantime, the Hampton Wick Cricket Club is anxious to get a portion of the ground in order for cricket during the coming season.

A Chair of Forestry at Edinburgh.—At a meeting of the Edinburgh University Court, on the 18th inst., a letter was read from the Treasury intimating that an advance of £7,000 by way of a grant from the Development Fund would be made to the University in aid of the endowment of a Chair of Forestry on the condition already accepted by the University—that the remaining £7,000 required was provided by the University from other sources. The Court resolved to institute a chair.

Appointment.—Mr. William Clark has succeeded Mr. Robert Walker as superintendent of the Aberdeen Public Parks and Gardens. Mr. Walker has retired after nearly half a century's service. His successor was for nearly five years in charge of Duthie Park, where he has done excellent service.

Public Gardeners' Increased Wages.—The Metropolitan Borough of Bermondsey has increased the wages of under-gardeners employed in the public gardens and open spaces to 45s. weekly. A war bonus of 20s. is also being paid to the whole of the garden staff.

Open Spaces as War Memorials.—At a recent meeting of the Metropolitan Public Gardens Association particulars were given regarding the planting of 41 acres of land acquired as a war memorial adjacent to Wimbledon Common, for which a sum of £7,000 is required. The Association draws attention to the advantages attaching to open spaces as war memorials.

Dwarf Rhododendrons.—In recent years collectors in Western China have sent home a large number of low-growing Rhododendrons that promise to be specially suitable and valuable for the rock-garden. In *Notes of the Edinburgh Botanic Garden* Prof. Bayley Balfour enumerates some thirty-four species belonging to the lapponicum section, all but three of which are found in China. Several of these dwarf Chinese species are in cultivation in this country, and one of the earliest introduced is R. intricatum. Seeds of this species were sent home by Mr. E. Wilson when collecting for Messrs. J. Veitch and Sons, who raised plants which flowered in March, 1907. A specimen was exhibited at the meeting of the Royal Horticultural Society on March 19 of that year under the name of R. nigro-punctatum, and was awarded the R.H.S. First class Certificate. On further examination it was found not to be that species but R. intricatum. R. intricatum is a densely branched shrub which in its native habitat grows from 1 foot to 3 feet high; it flowers profusely in a very early, small state. The small leaves are crowded and persistent, and are densely clothed with small scales on both surfaces. Terminating the branches are lilac-coloured flowers, mostly in clusters of five, and they are produced very freely during the early spring. The undivided bloom is about three quarters of an inch in diameter, and opens almost flat, with the stamens shorter than the corolla. The species has proved to be free-growing, easily propagated by cuttings and seeds, and adapted for growing in masses in large beds. Closely allied is R. fastigiatum (see fig. 33), one of Messrs. Bee's introductions, seeds having been sent home from Yunnan by Mr. Forrest. This species appears to be dwarfer and more spreading in habit, with smaller leaves and deep lilac flowers, in which the stamens much exceed the corolla. Another and still dwarfer species is R. prostratum, which Mr. Forrest found up to a height of 16,000 feet on the Lichiang range in Yunnan, where it grew only a few inches high, trailing over rocks at the extreme limit of vegetation. R. prostratum has hairy leaves and large, wide-open, rosy-purple flowers.

CONFESSIONS OF A NOVICE.

FROST AND THAW.

WHEN the thaw came, although the "bone" was still in the ground, I could not restrain my eagerness to put in operation my reconstruction scheme. Unfortunately the Ministry of Reconstruction had omitted to offer me guidance—at least, of the multitude of counsel which it has vouchsafed to us I have seen no pamphlet on the Reconstruction of the Rock Garden. So, free from Government control, I proceeded to carry out my own scheme in my own way. I did little, but I learned much. What I learned is, I suppose, only what every gardener knows, but nevertheless I set it down for the benefit of the rising generation of novices. Just now, of course, they will not read it, for they are engaged in explaining to us how inefficient we all are. It is good for us who have bored the young with advice, to get some of our own back, and they who have done the fine things in the war have a right to despise us who have only done the finicking things—grown food and suffered our hearts to break with the news of their suffering and loss. So though to me the flowers of my garden may never have the brightness they used to have, I still go on tending them, because some day, when the eager young have reformed the world and buried us, they, tired of their Titanic task, will come back to the garden, and perhaps love what we have lost. Besides, it is less tedious to go on learning as we go on living, and when all is said and done a story with a moral is less dull than a cinema. So to my morals! When, after moving freely through the patch of soil which I stirred last autumn, I broke the prongs of the fork in the unstirred frozen ground, I realised the value of the frequent stirring of the soil which all good gardening books recommend.

The frozenness of the unstirred soil when the stirred had thawed, showed well how the stirring helps the drainage—for the cause of the frozenness is to be attributed to the excess of water contained in the unstirred soil. I was pleased at this effort of reasoning, and remembered my school lessons on the latent heat of water, and Humboldt's explanation of the reason why baked Apples burn your mouth —because water takes a lot of cooling, and conversely a lot of heating. Thus I discovered why some of my choice things were looking miserable; their roots were rotten owing to the water-logged soil, now frozen, in which they were embedded. A little kindly stirring of the crust once or twice in open autumn and winter weather would, I think, have saved them. I should like to know the views of expert gardeners on this theory of what may be called the winter mulch. The summer mulch protects the plant from the risk of too little water, and the winter mulch from that of too much. What is the rate of heat-radiation from a finely broken surface in comparison with that from an unbroken surface of soil? In the case of a light soil which is rather late because of insufficient means of drainage, would it be better to stir the top 3 or 4 inches once or twice in late autumn or winter, and then to dig it in early spring, or to follow the—with me—usual practice of leaving it alone till digging time? What I gained in better drainage should I lose in increased loss of soluble food by the leaching action of winter rains? I don't think I could lose much more, for as it is I seem to lose everything delectable to plants, and must manure constantly to get any but vegetables fit for Liliputians. Some will say trench! But it does not seem as though trenching helped much in this light soil, which behaves like sand in summer and like clay in winter, when it covers itself with a skin and waterlogs itself.

The forcing effect of frost is always fascinating, and this year showed up beautifully in the Pear buds, which, dormant until the recent spell, now show their mosaic of brown and pearl. Now that they have signalled the return to life of garden trees, and with the Crocus sheaves appearing, the sleeping beauty of the garden is stirring in its bed, instinctively making ready to be wakened by the kiss of spring. To be candid, I plucked this pretty metaphor from the leaves of the *Gardeners' Chronicle.*

The last of the Leeks are off the lawn, and in their place I shall hope this spring to grow Red Fescue and Poa pratensis, and trust that my venture in vegetables may be rewarded by a better turf than languished on the lawn before the war taught us the virtue of cheerful sacrifice, and wore out our nerves so that we begin already to forget the lessons which it taught. *A. N.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Dimorphism in Polygonum amphibium.—It is well known to botanists and others that two forms of Polygonum amphibium are met with in a wild state. For some years the dry land form was recorded under the name of P. a. terrestre, but the name has been abandoned, in the belief that there is no permanency or distinctness between the two forms, but that one would give rise to the other if the conditions were reversed. I have not made the experiment any more than has Sir Herbert Maxwell (see p. 33), but in 1885 I gathered the two forms in such proximity that they could easily have been one and the same plant. They were certainly in one and the same colony. On the grassy bank of a canal, about 1 foot above the level of the water, the dry land form, with very short petioles and long, lanceolate leaves, was growing freely and flowering. Other stems from the face of the bank at the same spot extended over the water, and bore short, broad leaves with petioles 2 inches long. These stems were flowering even more profusely. It is my experience that the species always flowers most profusely when growing in water, and that acres of low-lying and slightly damp land may be more or less covered with the terrestrial state without showing a single spike of bloom. I have flowers, however, from a bank 6 feet above the level of a river. Alisma ranunculoides also has a marsh and a floating state when the water is sufficiently deep to lengthen the leaf-stalks. *J. F.*

Romneya Coulteri.—If your correspondent, *T. J. Hicks*, examines the tips of the growing shoots, he may possibly discover the cause of this plant "going blind." A very minute greenish caterpillar feeds on the embryo flower-buds (one grub to each bud), the foliage showing no damage at this stage. If this is found and destroyed in time the result will probably be a glorious blossom terminating every "branch." I have not discovered what fly or moth lays the egg. *M. C. H., Co. Dublin.*

—— I agree with Mr. T. J. Hicks that Romneya Coulteri is not worth the trouble of growing if his plants are the same as mine—i.e., seedlings. I have had two plants growing at the foot of a south-east wall in a narrow border for the past five years, and during that time, although good growth was made, both by cutting down the plants to the ground-line as well as treating them otherwise, I have not had six satisfactory flowers from them. Plants from layers or suckers taken from a good source previously flourished in the same site, and flowered continuously into the autumn. *E. M.*

Wireworm and Mustard (see p. 64). — Mr. Fryer states: "Wireworms will not eat Mustard if they can get anything else." It would be interesting to know if any of your readers hold the opposite opinion, that, indeed, the wireworm feeds on the Mustard so ravenously that they burst themselves. *Jonathan Fiona, Ultima, N.B.*

Gardeners' "Victory" Memorial. — I was especially interested to note the generous space given in the issue of February 1 to the report of the Gardeners' Royal Benevolent Institution. It has survived the war period, although the funds are a little restricted. Yet we note the same generous spirits are still at work, giving of their (shall I say in many cases) diminished incomes as freely as in past years. Gardeners throughout the country are greatly indebted to these gentlemen, who act so generously toward members of their profession. I doubt if any other profession can boast of such generosity; in connection with this charity a united effort should be made during 1919 to obtain subscriptions for the Institution from every gardener or past gardener in the country, to establish a reserve fund as a lasting memorial to those gardeners who have given their lives for their country during this terrible war. A little while ago I ventured to suggest the erection of a tablet in the Horticultural Hall to the memory of gardeners who had fallen in battle. This, of course, would be in addition to the greater memorial, which might also be shared by the Royal Gardeners' Orphan Fund. I venture to suggest that most gardeners would subscribe a little towards such a memorial as this. Other suggestions for a gardeners' memorial may be forthcoming, but the one I propose is worth consideration. Mr. Reginald Cory's action in contributing the sum of £500 to the Gardeners' Royal Benevolent Institution in spite of the fact that the Institution was unable to raise the sum he stipulated, and further to renew his offer for this year, 1919, was exceedingly generous. I only hope that with the aid of the festival dinner about to be resumed more than the stipulated sum may have been contributed. *G. A. Cranstone.*

Silver Leaf Disease.—About 16 years ago a Barrington Peach tree at Rotherfield Park developed Silver Leaf badly. The tree was growing under glass. I cut the most affected parts clean out, and then attended to the roots—in my opinion there lies the source of all the trouble—adding fresh and rich compost. The tree answered to the treatment, and made growth, and has borne good crops of fruit every year since, without showing any trace of Silver Leaf. *Wilmot H. Yates, Alton, Hants.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 11.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Col. H. Rawson, Messrs. W. Hales, W. C. Worsdell, and F. J. Chittenden (hon. secretary).

Nectria cinnabarina.—Mr. E. A. BOWLES showed a branch of an Acer covered with the numerous coral spots produced by this fungus in its fruiting stage. The fungus is exceedingly common on a variety of woody plants. It is a wound parasite, invading and killing the healthy tissue about the wound, and not producing its fruit until it has killed the wood invaded. The treatment consists of cutting out the infected portions well behind the part on which the fungus fruits are produced and behind any parts showing a brown discoloration in the wood.

Hardy Maize.—Prof. R. C. PUNNETT sent an exhibit showing ripe cobs of two varieties of Maize ripened in Cambridge, one yellow, the other cream, and both of the hard-corn type. These had been raised by him by crossing different varieties as recounted in *Gard. Chron.*, January 11, 1919. A Certificate of Appreciation was unanimously recommended for the work done by Prof. PUNNETT in raising these varieties.

Primula variabilis and Narcissus Tazetta var. —Mr. G. C. DRUCE sent specimens of the hybrid between Primula vulgaris and P. veris with small coloured flowers, often grown in gardens under the name P. variabilis, and found in abundance near Pulborough in an apparently wild state. He also showed a form of Narcissus Tazetta, near "Paper White," collected as an escape near Yiewsley, Middlesex.

TRIALS OF BRUSSELS SPROUTS AND CARROTS.

The following awards have been made by the Royal Horticultural Society after trial at Wisley:—

BRUSSELS SPROUTS.

Awards of Merit.—Dundee, sent by Messrs. Barr and Sons; Favourite, sent by Messrs. Artingstall.

Highly Commended.—Dalkeith, sent by Mr. Scarlett, Musselburgh; Holborn Exhibition, sent by Messrs. Jas. Carter and Co.; Rosny, sent by Messrs. Barr and Sons. *Commended.*—Aigburth Giant, sent by Messrs. R. Veitch and Son; King of the Market, sent by Messrs. Barr and Sons; Perfection, sent by Messrs. E. W. King and Co.; Darlington, sent by Mr. Scarlett.

CARROTS.

Highly Commended.—Early Frame, Early Queen, both sent by Messrs. Barr and Sons; New Intermediate, sent by Messrs. R. Veitch and Son. *Commended.*—Champion Horn, Improved Long Red Surrey, both sent by Messrs. Sutton and Sons, Reading; New Scarlet Intermediate, sent by Messrs. Sydenham, Ltd.; Perfection, sent by Messrs. Dickson and Robinson.

HORTICULTURAL CLUB.

FEBRUARY 11.—The annual general meeting of the Horticultural Club was held at Anderton's Hotel, Fleet Street, on this date. The president, Sir Frank Crisp, occupied the chair. The hon. secretary read a letter from the chairman and treasurer, Sir Harry J. Veitch, regretting his inability to be present owing to indisposition. The chairman announced that owing to difficulties of travel caused by the railway strike, the annual dinner fixed for that evening had to be postponed, and it was decided to hold it later in the year, May 20 being suggested as a suitable date. The annual report of the Management Committee was submitted, from which we extract the following :—

Notwithstanding the serious effect which the war has had on all institutions of a social character, the membership of the Horticultural Club is very little diminished. On February 26, 1918, the number of members was 193, and on January 28, 1919, it was 183. It may be stated that before the war, i.e., at the beginning of 1914, the total membership was 209, so that during the 4½ years of war the numerical strength has been diminished by only 26 members, including a number of deaths.

The arrangement made with the Farmers' Club to share their premises has worked very well, and the committee have been invited to continue it for as long as the members may find it convenient.

In June, 1918, the club sustained a severe loss in the death of the hon. secretary, Mr. R. Hooper Pearson. Mr. Pearson had endeared himself to all the members of the club, and his great interest in the progress of the club, and the earnest work by which he furthered its interests and gave it an ever-increasing popularity, left their mark on its membership and on its standing.

It will be remembered that in April, 1916, it was decided to contribute the sum of £50 to the R.H.S. War Horticultural Relief Fund, and this amount is now payable.

A luncheon for members and friends was arranged on October 8, at which forty were present, and another on November 5. Committee meetings were held on June 18, July 30, October 8, and December 3, 1918.

During Mr. Pearson's prolonged illness, his colleague, Mr. G. F. Tinley, assisted him in matters connected with the club, and took his place on several occasions at the meetings. On Mr. Pearson's death he was elected by the committee to fill the vacancy.

The committee hopes to arrange for a resumption of the monthly dinners and lectures.

The balance-sheet showed a balance carried forward to 1919 of £35.

Sir Frank Crisp, Bart., was re-elected president; Sir Harry Veitch was reappointed chairman and treasurer; and Mr. G. F. Tinley re-elected hon. secretary. The other officers and members of the committee were all re-appointed.

BRITISH CARNATION.

THE hon. secretary, Mr. T. A. Weston, informs us that the following new varieties of Carnations were registered with the British Carnation Society during 1918: *Mrs. Edward Douty*, seedling; crimson, very free. *Winter Glow*, seedling; glowing cerise (Award of Merit). *Brilliant*, seedling; glowing scarlet; very free (Award of Merit). (Registered by Stuart Low and Co.) *Marion Wilson*, seedling; maize-yellow, flaked red (Award of Merit). *Wivelsfield Beauty*, seedling; yellow, flaked pink; strong habit. *Sussex Pink*, flesh; suitable for planting out of-doors. *Toreador*, seedling; pale pink, flaked red; very strong. (Registered by Allwood Bros.) *Speckles*, sport from Lady Northcliffe; salmon, spotted dark pink. *Coquette*, seedling; heliotrope, cerise-pink centre. (Registered by C. Engelmann.) *Enid*, seedling; bright crimson; very free. *Romeo*, seedling; dark crimson; good habit. *Daydream*, sport from Mayday; deeper colour; very fine for all purposes. (Registered by W. E. Wallace.)

NATIONAL CHRYSANTHEMUM.

FEBRUARY 17.—Considering the inclement weather, the attendance at the meeting of the Executive Committee, held at 35, Wellington Street, Covent Garden, was good. Mr. Thos. Bevan presided. The members were in an optimistic mood, and entered heartily into the consideration of a forward programme presented by the secretary, which was endorsed. The programme includes an enlarged schedule of prizes for the November meeting, encouragement of early-flowering varieties, lectures to affiliated societies, and the publication of the Society's Transactions. All these items were agreed to in general terms, and referred to the sub-committees concerned for their consideration and report.

The Schedule, Finance, and Publication Sub-Committees were re-elected, and the retiring members of the Floral Committee were re-appointed, while Mr. Sargent, Kingston, was elected to fill a vacancy arising.

ROYAL SCOTTISH ARBORICULTURAL.

FEBRUARY 8.—The annual business meeting of this society was held at 5, St. Andrew Square, Edinburgh, on this date, the Duke of Buccleuch, K.T., president, in the chair. About 50 members attended.

The report of the Council showed that the membership was now 1,655, over 300 having been added as the result of a personal appeal by the president. The financial statement, which was moved by Mr. W. H. Massie, the convenor of the Finance Committee, showed that the society possessed about £2,400 of invested capital, and was in a better position financially than it had ever been before.

Sir John Stirling Maxwell, the Assistant Controller of the Timber Supply Department of the Board of Trade in Scotland, stated that the exhibit of home-grown timber which his department intended to set up at the Highland and Agricultural Society's Show in Edinburgh in July would demonstrate that the capacity of the Scottish soil for growing timber had been greatly under-estimated in the past.

Colonel Sutherland, of the Forestry Department of the Board of Agriculture for Scotland, said that ex-officers of the Army who might wish to apply for forestry posts would have to undergo a thorough course of technical education, but the number of men wanted for these higher posts would be very limited. He also stated that one of the difficulties in connection with immediate afforestation was the shortage of the seed reserve.

The following motion, which was moved by Mr. Geo. Leven, Bowmont Forest, Roxburghshire, was unanimously adopted :— "This meeting of the Royal Scottish Arboricultural Society, while cordially welcoming the appointment of the Interim Forest Authority, respectfully urges the Government to pass without delay the necessary legislation setting up a permanent Forest Authority with Local Executives, endowed with adequate funds and the fullest powers to enable it to carry out effectively a progressive forest policy for the United Kingdom, having regard to the extent of suitable land available in each country as well as to the timber requirements of the whole kingdom."

The Duke of Buccleuch was re-elected president; Mr. James Whitton, Superintendent of City Parks, Glasgow, was elected to the vacant vice-presidency; and the new councillors were Messrs. Wm. Gilchrist, Mount Melville; Geo. Leven, Bowmont Forest; J. F. Annand, M.Sc., Newcastle-on-Tyne; Alex. Finlayson, Newbattle; and A. B. Robertson, The Dean, Kilmarnock. The honorary secretary (Sir John Stirling Maxwell), secretary and treasurer (Mr. Galloway), honorary editor (Dr. Borthwick), auditor, and consulting scientist were re-elected.

SCOTTISH HORTICULTURAL.

FEBRUARY 1.—On the evening of February 1 Mr. Fife, the president, and Mrs. Fife, entertained the Council of the Scottish Horticultural Association in Ferguson and Forrester's Rooms, Princes Street, Edinburgh. Among the other invited guests were Sir Robert Greig, of the Board of Agriculture for Scotland, who proposed the health of the Association; Mr. McCallum, Edinburgh and East of Scotland College of Agriculture; Mr. Wm. Cuthbertson, and others. A most enjoyable evening was spent.

FEBRUARY 4.—The monthly meeting was held on this date. The occasion was the opening address for the session by the president, Mr. Robert Fife, but owing to a sudden attack of illness he was unable to be present, and only the formal business was transacted.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 10.—The monthly meeting of this society was held in the R.H.S. Hall on Monday, the 10th inst. Mr. C. H. Curtis presided. Three new members were elected. The death certificate of one deceased member was received, and the sum of £20 17s. 6d. was passed for payment to his nominee. The sick pay for the month on the ordinary side was £75 0s. 7d., and on the State Section £41 14s. 2d., and maternity claims £6. It was announced that the annual meeting will be held in the R.H.S. Hall on Monday, March 10th, at 7.30 p.m.

SURBITON, KINGSTON AND DISTRICT CHRYSANTHEMUM.

AT a general meeting of the above society (the first since December, 1915), held on the 12th inst., it was decided to hold a Chrysanthemum Show next autumn. Mr. J. Salter Cox, who presided, was elected president, and a committee was appointed. Mr. T. A. Hill, who has been secretary for many years, expressed his intention of relinquishing the office, and Mr. T. Smith was elected honorary secretary.

CROPS AND STOCK ON THE HOME FARM.

MUSTARD.

THE very interesting article by Mr. Fryer on p. 64 of the *Gard. Chron.* of February 5 is well worth the attention of all interested in land cultivation, whether as farming on a large or small scale, or as market gardening, or even as small-holdings and allotments. Apart from its value as the means of either killing or driving away wireworm, a full crop of Mustard is valuable from a manurial aspect. Mustard sown in July or August on stiff, badly-working land gives a heavy crop if assisted by 2 cwt. of superphosphate per acre at sowing time, spread broadcast in front of the seed. Such Mustard, ploughed in when 2 feet high, and thoroughly buried by the aid of the presser, very much improves the working of such soils by allowing a quick percolation of surplus surface water. It is surprising how much better stiff soil can be tilled if so treated, even after a crop of Wheat has been taken in the following August.

If such a field is required for spring-sown Oats, and is ploughed again in January, the tilth would be almost perfect for an Oat crop to be sown early in March. As a manurial agent I consider Mustard is more valuable ploughed in than fed off by sheep.

Farmers, except under special circumstances (shortage of food generally), do not highly prize Mustard for sheep, as it is considered to possess little "stay" or "proof," but with other food, such as Sainfoin or mature Italian Rye grass, the Mustard crop often helps to tide over a scarcity. Where the land is stiff the treading by the sheep is more injurious than beneficial. In the case of light soils, and especially chalk, the treading by sheep is beneficial, especially if Wheat is to follow the Mustard.

On some farms where sheep are not kept Mustard is the exclusive preparation for Wheat, and gives surprising results.

In a small garden or allotment Mustard grown and ploughed or dug in is an excellent manure, but it is rarely that space can be provided early enough for the crop.

Where wireworm, leather jackets, and other soil pests are numerous, and injurious to Carrots, Parsnips, Swedes, Spinach, and Brassicas, I strongly advise the use of Vaporite, as giving much less trouble and at a small cost. This

material should be sprinkled over the surface of newly dug ground and lightly forked or harrowed in seven days before sowing the seed; 2 cwt. per acre, or 1½ lbs. per rod, is sufficient. *E. Molyneux, Swanmore Farm, Bishops Waltham.*

TRADE NOTES.

Mr. R. F. Martin, for many years alpine and herbaceous foreman to Messrs. T. S. Ware, and recently in charge of Messrs. Toogood and Sons' nursery and trial grounds at Nursling, has entered the service of Mr. H. Hemsley, nurseryman, Crawley, Sussex, and will have charge of the alpines department.

A special sub-committee of the Chamber of Horticulture met on Thursday, February 13 (when Mr. Edward Laxton and Mr. Roots, of Messrs. Shawyer, attended to explain the present position of raisers of new varieties), and gave consideration to a scheme, drawn up by Messrs. Laxton Bros., and supported by other firms, to effect some kind of protection in the future.

The committee instructed the secretary to invite expressions of opinion on the existing grievances and the possibility of such being amended, to be sent to him at Norfolk House, Norfolk Street, Strand, forthwith. All raisers of new and improved varieties of fruits, vegetables, and flowers of economic importance are urged to write fully to the Chamber in order that the committee may arrange for a conference at an early date.

In reply to a question in the House of Commons as to whether, in view of the probability of the dumping of foreign fruit and vegetables in this country, the Board of Agriculture would take steps to arrange for preferential rates for fruit and market-garden produce grown in this country, Colonel Sir A. Griffith-Boscawen, Parliamentary Secretary to the Board, stated that it was not within the powers of the Board of Agriculture to determine railway rates or to arrange for preferential rates for home-grown produce, but they will continue their endeavours to ensure equitable treatment for British growers.

Obituary.

Sir C. T. Dyke Acland.—On the 18th inst. Sir Charles T. Dyke Acland died at Killerton Park, near Exeter, of bronchitis, aged 77 years. He took a great interest in horticulture and agriculture, and at Killerton he cultivated a large collection of trees and the rarer hardy plants. For many years he was a member of Parliament for the Launceston Division of Cornwall, and in 1886 he held the position of Secretary to the Board of Trade. As recently as 1917 he conveyed his rights in Exmoor to the National Trust.

Henry W. Wood.—Born in Newark in 1864, Mr. H. W. Wood went to America with his father, who founded the firm of T. W. Wood and Sons, of Richmond, Va. Mr. H. W. Wood eventually became the head of this horticultural business, and was at one time President of the American Seed Trade Association. He died suddenly at New Orleans on January 14, while on a visit to California for the benefit of his health.

G. H. Leak.—It is with profound regret we have learned of the great loss Mr. and Mrs. G. W. Leak, of Wisbech, have sustained by the death of their eldest son, which occurred on the morning of February 16. After leaving school, Mr. G. H. Leak was employed for two years in the seed department at Messrs. R. H. Bath's Floral Farms, Wisbech, and then spent two years on the seed farms of M. H. Desbois, Brain-sur-L'Authion, Marne-et-Loire. In May, 1917, he came home, enlisted in the Kensington Rifles, and in October of that year he went out to France, where he underwent special training in connection with the Lewis gun. His first engagement was at Vimy Ridge, and he fought in this and various other battles without being wounded, until the advance on August 8, 1918, when he received a severe wound in the thigh and was subsequently sent to Bangour Hospital, N.B., and afterwards to a hospital in Edinburgh. On recovering, he was transferred to an Agricultural Company at Peterborough, and finally came home to Wisbech on agricultural furlough. The end came with tragic suddenness. On Thursday, the 13th inst., he was taken ill with influenza, which brought on dysentery, from which he had suffered considerably in France, and to this he succumbed on February 16, at the early age of 22 years. He was a fine lad, beloved of all who knew him, capable and modest. Readers will join us in expressing deep sympathy with Mr. G. W. Leak and his family in their great and sudden loss.

ANSWERS TO CORRESPONDENTS.

Dead Bees: *T. S. T.* We have examined the bees superficially and find no symptoms to attribute their decease to Isle of Wight disease. This complaint can only be discovered by a careful microscopic examination of the bees. The death of bees may be due to no special cause. Since the outer frames were so mouldy, it would be wise to put the stock into a clean, dry hive, with new, dry quilts. It would be wise, also, to perform the operation in the sunny summer-house, as you suggest, choosing a bright day, and doing the work as quickly as possible, to conserve the heat and to cause as little disturbance to the colony as possible, for bees should not be manipulated in winter except under the most urgent circumstances. Get everything ready that will be needed before opening the hive. Too many warm quilts of non-conducting material can scarcely be used.

Dwarfness in Plants: *V. R.* Dwarfness in some cases is an inherited character; for example, dwarf (Cupid) Sweet Peas and dwarf culinary Peas. The general explanation given is that stature of plants depends on, say, two factors: if both are present = tall; if one only, intermediate; if both absent = dwarf. In other cases dwarfness of habit is apparently due to environmental influence, e.g., in arctic regions. Artificial dwarfness, e.g., of Japanese Conifers, is said by some to be due to special methods of cultivation—restriction of root space, but by others it is said to be brought about by rooting a lateral branch of limited growth and potting it.

Eucalyptus: *H. J.* The name of the fruiting spray you sent is Eucalyptus amygdalina, and it was probably part of a recent consignment of cut branches received from the Riviera. The plant is a native of New Zealand, and although generally considered to be one of the hardiest species, it would scarcely withstand the winters of your locality—such weather as is being experienced at the time of writing would, for instance, be fatal. If you possess a greenhouse of moderate height, seedling plants could be very easily grown in it, though they may not blossom so freely as the examples which are now to be seen in the leading florists' shops. Seeds should be sown shallowly in light soil in the spring, and the receptacles placed in moderate warmth. Seeds of all Eucalypti received in this country are often rather slow in germination, but a goodly percentage may usually be relied upon to grow within a few weeks of sowing. When large enough to handle the seedlings should be potted singly into thumb-pots, using a compost composed of leaf-mould, loam, and sand in equal proportions. In due course transfer the plants to larger pots, increasing the proportion of loam in the compost, and potting more firmly. During the winter the plants may be stored in a cool greenhouse, but should be placed out-of-doors for at least seven months of the year. After the plants have produced their adult leaves, which are of the shape and texture of those on the spray you send, flowering may be hastened by pruning the bushes in spring just before growth recommences. Many species of Eucalyptus, including E. amygdalina, may be used in summer bedding with good effect.

Fleur de Lis: *J. M.* This is a French term for the Iris, stated to be derived from Fleur de Louis, from its having been assumed as his device by Louis VII. of France. In France the appellation is usually referred to Iris germanica, and sometimes to the common yellow Iris, I. Pseud-acoris.

Greengrocer's Business: *L. F. B.* By taking an empty shop you are adopting the best method of starting a greengrocer's business, provided the demand exists for an opening of this description. Your having been a lifelong gardener will certainly be a qualification, as it will help you to judge the best vegetables, flowers and fruits to meet your customers' requirements. Always bear in mind that "it takes a good salesman to sell inferior produce, but good ware sells itself." If you cannot obtain produce to stock your shop locally you could obtain it from Covent Garden Market or Kew Bridge Market; the former market always provides the best selection. If there are market growers in your neighbourhood it would perhaps be possible to obtain supplies delivered direct to you at market prices, which would save you cost of cartage, and the vegetables would be fresher than when obtained through a large market. It is also absolutely essential that in addition to gardening experience one should possess business ability, foresight, reliability, and sufficient capital to carry over the period of establishment. In purchasing do not overstock at the commencement, particularly with greens and choicer vegetables. Bear in mind the fact that the fresher you can supply vegetables to the customer the better and quicker will your business be established. It is necessary for you to obtain a licence from your local authorities. Make yourself acquainted with the Potato, Apple, and other Orders, market weights and measures, that are connected with your proposed trade. At the commencement you will probably find progress slow, but, with energy and ability, a fair business should be worked up in a few months. Should any part of the venture prove a failure, cut it at the earliest possible moment. It is generally a good policy to conduct a fruiterer's and greengrocer's business in conjunction, in preference to one section alone.

Hives Infected with Isle of Wight Disease: *G. H. S.* The quilts and frames should be destroyed, but the hives may be retained if they are treated, both inside and out, with a solution made as follows:—Mix one part of Calvert's No. 5 carbolic acid with two parts of water, and work the liquid into all cracks and joints with a paint brush. Use the disinfectant very liberally. Leave the hive open and exposed to brilliant sunshine until it is quite dry and free from odour, then paint the outside in the usual way, and it will be fit for use in May. Hives can scarcely be placed in too much sunshine. Remember that strong carbolic acid will burn the skin, and should be used with care.

Names of Plants: *E. S.* 1, Eupatorium micranthum (syn. Weinmannianum); 2, Cytisus (Genista) fragrans.—*H. S.* 1 and 2, Cypripedium insigne; 3, Masdevallia Schlimii; 4, Begonia semperflorens gigantea.—*C. L.R.S.* Varieties of Veronica Andersonii, one the variegated form.

Re-filling Empty Boiler and Pipes: *S. J. B.* So far as possible the movable parts should be cleaned inside and every part should be tested by tapping to discover any faults. All valves and air-taps should be examined and put in order before the boiler and pipes are filled with water, and the air taps should be left open while filling is proceeding. Start with a small fire. If everything appears satisfactory gradually work up a vigorous circulation of water by increasing the heat; then test the water by means of the draw-off tap, and if it is very dirty let it run away gradually, but keep the feed-box filled, until the water is clean. Some joints may have to be re-packed if they leak under the pressure of highly-heated water.

NO Garden Complete without

JOHN K. KING & SONS' LORD KITCHENER PEA.
Unquestionably the finest first-early Wrinkled Pea. The pods frequently attain to over six inches in length, and are filled with from 10 to 13 large Peas of delicious flavour. **Price per packet, 1/-; per pint, 2/8; per quart 5/-**
"Your Pea Lord Kitchener is one of the finest early Peas in cultivation. It was gathered on June 30th. It is of exceptionally fine quality and very productive."—From Mr. H. McCulloch, Gardener to the Rt. Hon. Lord Cadogan.

JOHN K. KING & SONS' IMPROVED LONG DARK-RED BEET.
A remarkably fine stock. The flesh is of exceedingly dark colour and of delicious flavour.
Per packet, 6d.; per ounce, 1/6

JOHN K. KING & SONS' PRIDE OF THE MARKET BRUSSELS SPROUTS.
Produces large solid sprouts, delicious in flavour, which come early. For market purposes it will be invaluable on account of the solidity of the sprouts.
Per packet, 6d.; per ounce, 1/6

JOHN K. KING & SONS' ELEPHANT PRIZETAKER RUNNER BEAN.
The largest and handsomest Runner Bean, and unsurpassed for length of pod and delicious quality. The pods frequently grow 16 inches in length, and are indispensable for Exhibition.
Per pint, 2s.; per quart, 3/6
"Your Elephant Prizetaker Runner Bean is the finest Runner Bean I have seen. It is wonderfully prolific, large and handsome shape."—From Mr. Carr, Gardener to the Rt. Hon. Lord Iveagh.

JOHN K. KING & SONS' EARLY SNOW QUEEN BROCCOLI.
For Autumn use no variety approaches this. It matures very quickly, the heads are firm in texture and snowy-white. Sown in March it will be ready to cut at Michaelmas.
Per packet, 6d. & 1/-; per ounce, 2/6

JOHN K. KING & SONS' READING DEFIANCE CABBAGE.
The hearts are wonderfully solid, tender, crisp, and of delicate flavour. Its merit consists in the short time it takes to mature. If sown in February and March, heads may be cut in July; and sown in August, it is ready for cutting the end of May.
Per packet, 6d. & 1/-; per ounce, 1/6
"Please send me another packet of your Reading Defiance. It is the best type of garden Cabbage I ever had."—From Mr. W. Goodman, Winslow.

JOHN K. KING & SONS' READING PRIZE WINNER INTERMEDIATE CARROT.
The best type of Red Intermediate Carrot. The skin is a bright crimson, has very little core, and the flesh is of close texture. It is unsurpassed for Exhibition. **Per ounce, 1/3**

JOHN K. KING & SONS' PERFECTION MARROW PARSNIP.
The most perfect Parsnip in cultivation. It is clean and handsome in shape, free from fangs, and of delicious marrow flavour, while as an Exhibition variety it is absolutely unequalled. **Per ounce, 9d.**

JOHN K. KING & SONS' SNOWDONIAN CAULIFLOWER.
A distinct variety, producing enormously large, very firm, and snow-white heads.
Per packet, 1/-, 1/6, and 2/6

JOHN K. KING & SONS' MATCHLESS WHITE CELERY.
This is the best of the white Celeries. It is remarkably solid and of splendid flavour.
Per packet, 6d. & 1/-

JOHN K. KING & SONS' GIANT SELF-HEARTING WHITE COS LETTUCE.
Unsurpassed in quality, grows to a large size, is self-hearting, requires no tying, and is very solid and crisp. **Per packet, 6d. & 1/-; per ounce, 2/6**

JOHN K. KING & SONS' WONDERFUL CABBAGE LETTUCE.
The best Cabbage Lettuce ever introduced. The hearts are large, wonderfully solid, and very compact. The quality is exceptionally fine, beautifully crisp and of splendid flavour.
Per packet, 6d. & 1s.; per ounce, 2/-

JOHN K. KING & SONS' EXHIBITION GLOBE ONION.
Somewhat oval in shape, with bright yellow skin and strikingly handsome. It is frequently grown from 2 lb. to 3 lb. in weight, and is an enormous cropper. Its mild and delicate flavour will ensure for it general cultivation. **Per packet, 1/-, 1/6, 2/6, and 5/-**

MARKETS.

COVENT GARDEN, February 19.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

Hyacinths, Roman, 12's, per doz. bun.	3 6- 4 0	Violets, single, per doz. bun. ...	6 0 10 0

REMARKS.—Supplies of cut flowers this morning were considerably shortened owing to the severe weather, and a rise in prices may be expected, especially for white flowers. Daffodils are arriving in excellent condition; the varieties offered are Emperor, Golden Spur, Henry Irving, Princeps, and obvalaris. Pheasant-eyed Narcissus is sufficient for the demand. Richmond is the leading variety in Roses, and soon sells at high prices. A large supply of white Lilac has arrived from Holland during the past fortnight, also a few white and coloured Tulips. The supplies from the Channel Islands have been greatly reduced during the past week, and the supplies from this quarter are likely to be limited for some time. The whole consignment of French flowers which arrived this morning were frozen hard and unfit for immediate use. Paper-white Narcissus rose to 30s. per pad of 48 bunches on Saturday. Large portion of last week's arrival consisted of Acacia (Mimosa). Several pads of double white Stocks were received last week in good condition, and sold quickly. Anemones and Violets are more plentiful.

REMARKS.—The market is fairly well supplied with black Grapes, and there are good samples of Almeria Grapes (Spanish) on sale. Californian Pears obtainable consist of the varieties Easter Beurré and Winter Nelis. Other fruits on offer consist of the following:—Oranges (Spanish), Seedless Oranges (Californian), Tangerines, Lemons, Pines (Azores), and Bananas. Teneriffe Tomatos are on offer. Forced vegetables continue a limited supply. *E. H. R., Covent Garden Market, February 19, 1919.*

THE WEATHER.

THE WEATHER IN SCOTLAND.

January was a depressing month, mild, but wet and dull. Rain or snow fell on twenty-one days, with a total of 2.78 inches; the first day of the month being the wettest day, with 0.77 inch. Only 35.4 hours of sunshine were recorded, being an average of 1.1 hour per day, and a percentage of 15. The brightest day was the 18th with 6.7 hours. There were fifteen sunless days. The mean barometric pressure was 29.67 inches, with a highest of 30.60 inches on the 24th, and a lowest of 28.77 inches on the 6th. For the month the mean temperature was 35.6°, the mean range 9°, and the absolute range 23°. A highest maximum of 44° was recorded for the 9th and 24th, and a lowest minimum of 21° for the 19th, while the lowest maximum was 35° on the 19th, and the highest minimum 38° on the 10th. The means for the maximum and minimum were 40° and 31° respectively. On sixteen nights the temperature fell below the freezing point. For the month the relative humidity of the air was 89 per cent. On the grass a mean minimum temperature of 28° was recorded, the lowest reading being 16° on the 19th. There were twenty-one nights of ground frost. At 1 foot deep the soil temperature remained constant at 34°. The prevailing winds were southerly and westerly. A rainbow was seen on the 28th and a display of aurora on the 31st. *James Malloch, Director of Studies, Training College Gardens, Kirkton of Mains, near Dundee.*

List of Vegetable Seeds free.—TILLIE, WHYTE & CO., Seed Growers, 12, Melbourne Place, George IV. Bridge, Edinburgh.

SILVER FIRS: 200,000 Plants for Sale. —Sample on application to E. G. CUBITT, Honing Hall, Worstead, Norwich.

PEARS.—Fruiting horizontally trained specimens; well transplanted, and true to name. —Measurements and prices from WILL TAYLER, Hampton, Middlesex.

RHUBARB. — Champagne, clumps for forcing, 10s. per doz., 80s. 100; planting sets, 3s. dozen, 25s. 100; Dawes' Champion, 35s. 100 sets; on rail, for cash only.—J. HANDSCOMBE, F.R.H.S., Feltham Nurseries, Middlesex.

GENTIANA VERNA, 12 clumps 5s., free, 3 Crested Royal Flowering Ferns, 4s.; 6 Dryas Octopetala, 4s.—O'KELLY, Botanist, Ballyvaughan, Ireland.

GENERAL FOCH, new Dwarf Nasturtium, Seed Packet, 1s. and 1s 6d.; most beautiful variety.—D. DAVIES, Derwydd Cottage, Cemetery Road, Ogmore Vale.

RIBES, Scarlet Flowering, 3 to 4ft., 3s. doz., 20s. 100 strong plants.—SYDNEY SMITH, Tansley "Old" Nurseries, near Matlock.

SEED POTATOS.—Epicures, 10s. cwt.; Sharp's Express, 14s.; Maincrops, 8s. 6d. Send for price-list. W. J. PLAYER, High Ridge Farms, Haddenham, Cambs.

RARE SHRUBS and TREES from China, Japan, Siberia, America, &c.; catalogues on application.—ALDER, River Nursery, Iver Heath, Bucks.

HAZEL, 2 to 3 ft., transplanted, 30s. 1,000, 5s. 100.—SYDNEY SMITH, Tansley "Old" Nurseries, near Matlock.

AUSTRIAN PINES, selected bushy, 3ft., 6s. dozen, 40s. 100. SYDNEY SMITH, Tansley "Old" Nurseries, near Matlock.

ENGLISH OAK, 2 to 3ft., stout, well rooted plants, 5s. 100, 40s. 1,000.—SYDNEY SMITH, Tansley "Old" Nurseries, near Matlock.

PLANTS, &c., WANTED.

WANTED, LARGE PLANTS for Conservatory decoration, such as Cobaea Scandens Variegata, Tree Ferns, Camellias, &c.—Particulars to GEORGE BURY, Arley Nurseries, Mellor, near Blackburn.

WANTED, large Kentia Fosteriana Palms, from 5 to 25ft in height; large, well-coloured Dracaenas and Crotons; for cash or exchange.—ROBERT GREEN (1911), LTD., 28, Crawford Street, W.

WANTED, good BULBS—Calanthe Veitchii, Vestita lutea and rosea.—Quality and price, A. E. BULL, Bonis Hall, Prestbury, Cheshire.

WANTED, two large Double White Camellias in pots or tubs.—Size and price to FRANK LEES, Florist, Reading.

WANTED, Thorn Quicks, Native and Japanese Larch and Sitka Spruce all sizes. Please quote, stating probable quantities, lowest nett cash prices for delivery, in 10,000 lots.—W. POWER & CO., Waterford.

WANTED, PHOTOGRAPHS of good flowering specimens of Hardy Trees and Shrubs; Hardy Perennials; Rock Plants; well fruited Cordon, Bush and Espalier Fruits, must be suitable for reproduction.—Particulars and prices to Box 331, 41, Wellington Street, Covent Garden, W.C.2.

MISCELLANEOUS.

GENUINE OLD YORK STONE PAVING for Rose Walks, Terraces, Lily Ponds, &c.; rectangular or crazy; delivered in large or small quantities.—H. BROOK, Quarry Owner, 40, Valley Road, Streatham, S.W.

SHANKS' LAWN MOWER, 18 in., with box, complete, Patent Chain Cover, excellent condition, £8 8s. Several other Secondhand Machines, various makes.—WM. BIGNELL & SON, North Road, Highgate, N.6.

GALVANISED TANK (second-hand); good condition; 4 ft. × 3 ft. × 2 ft. 8 in., capacity 200 gals., £3 10s. Quantity of 3 in. and 4 in. H. W. Pipes, Screw-down Valves, Bends, etc. State requirements. WM. BIGNELL & SON, North Road Highgate, N.6.

LOAM, Kettering best quality, for Vine and Peach borders, 'Mums, Tomatos, Cucumbers and Melons; nothing better for Carnations; loaded 4 to 12 ton trucks.—JOHN DON, 78, Derby Road, Nottingham.

FOR SALE, new Corrugated Iron Sheets, at following prices:—6ft. 6s., 7ft. 7s., 8ft. 8s. 2d., 9ft. 9s. 3d., 10ft. 10s. 6d.; carriage paid; immediate deliveries; all painted, ready for fixing. Apply, BUILDER, 48, Well Street, Hackney, London.

GLASSHOUSES for sale; also Garden Lights, Glass, Boilers, Pipes, Fittings Standpipe Valves, Hose, &c.; price against specification.—C. A. CHRISTIANSEN, Southall.

"PESTITE" kills wireworms, rookworms, cockchafer grubs, Julus worms, and other soil pests; also "club root" and other fungoid diseases. Price: 28lbs. 5s. 6d., 56lbs. 7s. 6d., 112lbs. 10s. 6d., 1 ton £8, all carriage paid, from G. LANG & SONS, LTD., Hounslow, Middlesex.

BIRCH BROOMS, 7s. dozen; Pea and Bean Sticks, 10s. 100 bundles; Rose, Dahlia and Plant Stakes, 3s. 6d.; Bean Rods, 3s.; Tree Stakes, 6s.; all 100; Poles and Posts for Pergolas, Arches, &c., 7d. each in Ash, Birch, Chestnut, Oak, on Rail.—H. SELL, Elmbrook Road, Cheam.

10FT. KINNELL'S HORIZONTAL TUBULAR BOILER and 700 feet 4in. Hot Water Piping.—CRISP, 39, Laitwood Road, Balham, S.W.

WEEDS! WEEDS! WEEDS!

NOW is the time to kill them. If your paths are cleaned now they will remain clean for the best part of the year. Our WEED KILLER is safe to handle.

CHEAPER THAN HOEING.

Will not harm birds or animals; is a powder; only requires sprinkling on the weeds.
1 cwt. Sacks, 20s., free on rail, London.
CLEVELAND & CO., 12, GREAT QUEEN STREET, KINGSWAY, W.C.
Agents wanted.

FRENCH GARDEN LIGHTS, perfect condition, 3, price £2; 12, price £7 5s.; Cloches, doz. £1, 100 £7 10s.—MISS SUFFERN, Tiptree, Essex.

BIRD'S BATHS, Garden Vases, Sun-dials, Vegetable and Flower Seeds. Catalogue (No. 3) free.—MOORTON, 5, Thornton Avenue, Chiswick, W.4.

BEST ready mixed PAINT, in 7 and 14lb. tins; Varnishes, Enamels, and Brushes. Prices on application.—A. GODSALL, 78, Rolls Road, London, S.E. 1.

TARPAULINS, Garden Barrows, and Wire Netting for sale; S.H. Tarpaulins and new Waterproof Sheets; also new Barrows and Wire Sheep and Rabbit Netting.—For particulars, write JOHNSTON, 12, Broughton Road, Croydon.

CARBOHYDRATE MANURING AND THE RUBBISH HEAP.

ORGANIC manures, which are much in vogue at the present time, have chiefly been advocated from the nitrogen point of view. Some experiments which I commenced in order to elucidate certain points in soil analysis were eventually directed towards the determination of the effect of fermentations of carbohydrate material (starch and sugar) in soil samples upon the amounts of "available" phosphoric acid and potash. It was hoped to make a number of observations upon soils of various geological origin, and a collection of several was made, but the war started and interfered with including in experiments so complete a series as was intended. The present importance of the manure question may make the publication of some results useful, even if only to stimulate work on similar lines on a larger scale than can be attempted single-handed.

In most cases the soils were taken from the top nine inches of old pasture land for the sake of uniformity. Whilst still fresh, they were sifted through a 3 m/m gauze and quantities of about 150 grms. weighed out; about 1.2 grms. of starch (in earlier trials cane sugar), *i.e.*, to make about one per cent. on the air-dry weight, was added simply or with further addition of one per cent. calcium carbonate to duplicate samples. The air-dry weight was determined. The fermentation lots were each given 100 cc. of water, and then left at room temperature for bacterial action to proceed. Eventually water was added to make up to tenfold the air-dry weight and a corresponding amount of citric acid to make the standard one per cent. solution. Also citric extracts were made of the unfermented soil; it seemed undesirable to introduce factors other than those of citric acid extraction or comparative values would be destroyed.

The results which are due to the survival of and activity of the bacteria which were present in the different samples no doubt would differ from those obtained from soil *in situ*, chiefly perhaps from the oversaturation with water in the trials, without which it would be difficult to attain uniformity. The odours developed during the fermentations showed that markedly different bacteria were at work in the various samples:—

Source.	*Formation.*	*Odour developed.*
Farm C.—Long-neglected pasture	Old red sandstone	Very strong butyric.
Farm W.—Manured orchard pasture	Ditto.	Indol-like, eventually stale, sewer-gas-like.
Budleigh.—Recently-ploughed pasture	Bunter Triassic	Slight, butyric.
S. 1—Orchard pasture	Granitic	Sweetish, later faint indol.
S. 2—Garden soil near by S. 1	Ditto.	Sweetish, no indol.
Alpine.—Le Lautaret	Igneous	Mawkish and musty.
Alpine.—M. Cenisio	Limestone	None distinctive or marked.
Brecon Beacons. Hill pasture	Black acid, peaty layer overlying old red sandstone	Mawkish and musty.
Netley.—Old pasture	Flint gravel drifts	Slowly developed slight butyric.

It may be noted that in all cases the liquid eventually became strongly alkaline, any initial acidity having been overcome, as is the case with pathogenic bacteria when carbohydrate material is not too abundant.

In regard to phosphoric determinations in general, it is unfortunate that they are largely unreliable because the prescribed routine includes an actual burning of the organic material (including a large quantity of citric acid), and this causes appreciable, if not often important, losses. In order to avoid such losses, the "incinerations" have been done by means of nitric acid with the help of a slight amount of concentrated sulphuric acid; in very ferruginous soils a certain amount of ferric phosphomolybdate is usually carried down so that reprecipitation is necessary. Further, care must be taken during the citric acid extraction to avoid undue shaking, such being limited to a mere mixing to ensure uniformity; and repeated sedimentation is preferable to filtration. The work of Dr. E. J. Russell and J. A. Prescott (*Jl. Agric. Sci.* VIII, 1916, p. 65) has shown the serious loss of phosphoric acid which ensues after vigorous shaking, especially with inorganic acids; though these authors elaborately ascribe the loss to "absorption," it seems likely that it is merely a case of surface aggregations of colloids as described by W. Ramsden (Separation of solids in the surface layers of solutions, etc., *Proc. Roy. Soc.* vol. 72, 1903, p. 156), who was able to obtain almost complete separation of certain colloid materials by means of simple shaking. It seems not unlikely that in the case of the shaken soil extracts some colloid silico-phosphoric complex was involved.

PERCENTAGES ON AIR-DRY SOIL.

Soil.		*Phosphoric Acid.*	*Potash.*	*Silica.*
Farm C.	Citric Ext. ...	0.0075	0.0169	0.0428
Jan. 1914	Ditto. after ferment	0.0096	0.0879	0.0768
Farm W.	Citric Ext. ...	0.0079	(Not determined)	0.0472
Jan. 1914	Ditto after ferment	0.0243	,,	0.084
	Ditto. ditto. ... (Stood 40 months)	0.0252	,,	0.084
Budleigh	Citric Ext. ...	0.0121	,,	0.098
Oct. 1915	Ditto, after ferment, starch only	0.0338	,,	0.135
	Starch & $CaCO_3$...	0.0366	,,	0.176

It will be seen that the amounts of "available" phosphoric acid and potash—that is, those amounts taken up by standard citric acid extraction—may be very appreciably increased by the soil having undergone a fermentation process with its own bacteria or some of them. But to my mind, of greater importance from the analytical point of view for an understanding of soil chemistry is the increase in soluble silica, for it points to a loosening of the bonds of some silica complex to a more soluble form. Soil chemistry and soil analysis grope in the dark until we have some insight and means of recognition of the composition of silica complexes, on the one hand with alumina, iron, etc., on the other with phosphates, chlorides, etc., not to mention organic components. It is generally admitted that chemical soil analyses leave much to be desired, and indeed are of little value unless the process used is given, and I imagine that this condition will persist until we can estimate the various useful and useless silica complexes and the liability of constituents to form or destroy these complexes when manures of sorts are added. Whilst some tend to decry the chemical side of the soil problem, it surely cannot be a matter of indifference when one soil contains 1% of potash and another but a mere fraction of that amount; what is wanted is some scheme to cause the former soil to yield up its potash rather than adding more, as must be done to the latter; so far, amelioration with lime is our chief standby. And here I may note that the addition of carbonate of lime aided the fermentative liberation of phosphoric acid (*vide* Budleigh above), whilst an addition of 1% quicklime to Farm W. soil only raised the phosphoric acid to 0.0118 (as against 0.0243 with the fermentation) associated with which was a slight depression of the solubilised silica, viz., 0.045 (as against 0.0472 unfermented, and 0.084 fermented); Farm C. soil behaved similarly.

It would be imprudent, if not impossible to give an account of the chemical changes which occur during these fermentations whether in the laboratory or the field. But one may broadly outline some of the factors and probabilities.

(1) The nature of the bacteria flora will direct changes one way or another. The simple test of the odour liberated, which is noted above, forms a rough index. And a wide field for enquiry is open by trials of the mixed flora of dungs of various animals on given soils.

(2) The nature of the fermentable or putrescible material present or added to the soil and also the amounts thereof will be of importance, for instance in favouring or inhibiting certain primary and secondary products, such as organic acids or eventual salts thereof, which may, of themselves, have some direct solvent powers on soil constituents.

(3) The chemical nature of the simple and complex bodies present in the soil. Amongst these it may be that substances present perhaps only in small or minute amounts may play an important part (catalysts) in effecting changes which are not produced, or only in a much slower manner, in their absence.

At any rate, the reducing action in many early stages of fermentations must be of importance, as when the less soluble iron (ferric) becomes reduced to more soluble iron (ferrous) compounds, or sulphates reduced to sulphides, which will have a direct effect upon some other compounds. The recent work on the direct effect of calcium sulphide used as an ameliorating agent, and the older prac-

tice of using green copperas (ferro sulphate) may be mentioned in this connection.

The practice of green manuring or digging in a green crop raised specially for the purpose supplies more readily fermentable material than half-rotten straw or peat-moss litter; or again, than the sawdust of recent stable manures. The report of the results following fallowing of the Hoos field (Rothamsted Ann, Rep., 1913), and the heavy crops obtained thereafter may be placed in the same category.

Next I come to the rubbish heap or "Compost," especially when built up on the plan much adopted in France of placing alternate layers of refuse and soil, or when containing a quantity of uprooted weeds with adherent earth; here conditions are favourable to decomposition of insoluble mineral compounds as in the bottle in the laboratory. Having such considerations in mind, and having been unable to get stable manure except at prohibitive rates for cartage, I cast round for a means of making the compost more valuable. The procedure adopted was to sprinkle the material as it was turned over layer by layer with basic slag in order to enhance the phosphorus content and in the hope of causing this costive agent to yield its virtues in readily available form. At the same time a sprinkling of lime was given, and through the early summer a covering of lawn mowings was added to kill the superficial growth of weeds and also retain heat in the heap. Though no analyses have been done and no control observations were possible—in fact the whole preparation was done in a purely arbitrary way—the procedure seems commendable, and where applied the various vegetables have done well, Cauliflowers perhaps particularly.

It was intended to make some observations on laboratory fermentations of basic slag, with carbohydrate and nitrogenous pabulum for the mixed bacteria of various dungs, but hitherto it has not been possible to carry these out, so that I am not able to indicate the lines on which a complete or nearly complete liberation of the phosphoric contents may be most readily attained. With regard to potash in the weed heap, probably there will be a sufficiency among the varied constituents, but it would be profitable to know analyses of ordinary weeds, such as Groundsel, for it might sometimes be profitable to allow high-potash-collectors to grow a bit before applying the hoe and rake. If desired, bonfire ashes could be added to the compost. The following figures are recalculated on the dry weights from the compendium of analyses given by Roberts (*Fertility of the Land*, Macmillan Co., New York, 1911):—

Percentages on the Dry Weight of the Mater ls

	Phosphoric Acid.	*Potash.*
Alfafa (hay)	0.72	2.11
Apple prunings	0.24	0.24
Beech Leaves (August)	0.41	1.0
Beet (Leaves)	0.82	5.84
Buckwheat (hay)	0.86	3.42
Cabbage...	1.56	3.68
Lettuce	0.43	2.3
Lupine (Yellow)	0.29	2.11
Mustard (White)	1.08	1.82
Oak Leaves (? fallen)	0.24	0.42
Pea ("Hay")	0.82	2.81
Pear (Prunings)	0.25	0.50
Potato (Haulm, July)	0.77	2.45
Rhubarb (Stem and Leaves) ...	0.3	4.32
Spinach	1.0	1.68
Tobacco (Stems and Leaves) ...	0.91	5.08
Tomato (Vine)	0.24	1.47
Well-rotted Ordinary Manure ...	1.43	2.38
Somewhat Rotted Ditto.	1.01	2.52
Fresh Ditto.	0.72	1.80

It will be seen that whereas the phosphoric contents generally fall below that of manure, in some cases the potash is well above. Beet leaves, Tobacco, and Rhubarb may be noted as great potash collectors, and it would be an important and interesting problem for the botanical physiologist to determine why these plants can or like to extract so much more potash from the soil than certain other plants. Analyses of the ornamental species of Tobacco would be also interesting as a possible means of adding to the potash value of the compost by growing them in all odd corners for the purpose

It is sometimes recommended to dig in Mustard, Spinach and Buckwheat as green manures: the potash and phosphoric values of these are good, particularly the potash in Buckwheat.

In testing a soil, especially one which has a rich reserve of phosphorus or potash, it may be worth while to determine the effect of a "fermentation" test, and thence infer that the addition of fermentable material (fallowing or green manuring) will be profitable, as an addition to, or alternative to, the incorporation of actual manure. It may be pointed out that this process is carried out by nature in many cases for the nutrition of the young seedling where the seed is surrounded by a fruit pulp of sugary material (Apple, Plum, Pumpkin, etc.). But, of course, it must be assured that a sufficiency of lime (*i.e.*, carbonate) is present to annul the tendency to harmful sourness. A friend who farms in this neighbourhood reckons that he had one of his finest crops of Mangel Wurzels in a field in which he had ploughed a considerable quantity of straw which he could not otherwise use; this, perhaps, was due to an "availabilising" of some of the residual artificials which had been applied in the past, and of which only a part is extracted by the crops. *H. E. Durham.*

A REVIEW OF THE YELLOW ROSES.

(*Concluded from page* 81).

Duchess of Wellington (1909) is a beautiful flower, and the Rose a good bedding variety in fine weather, the flowers, of the decorative class, being a deep saffron-yellow with an orange outer surface. The petals, however, will not stand rain, and if wet weather occurs while they are opening they become glued together, and the flower is completely spoilt.

1910 was a great year for yellow Roses, and produced no fewer than five which are worth mention.

Arthur R. Goodwin, coppery-orange, is very beautiful in the bud stage, but opens to a flat flower, the centre petals being short. Lady Hillingdon is a bright orange-yellow, and a most satisfactory bedding Tea. The flowers, however, are thin and not full enough for the exhibition box, but it is constantly seen in decorative stands, and is amongst the best of its class. Alice de Rothschild is another yellow Tea Rose of this year, and at its best is a deep citron-yellow, but it not infrequently appears as a less satisfactory colour.

The Rose of the year was undoubtedly Rayon d'Or, which is a wonderfully bright yellow, between gold and canary. A bed of it in the garden, particularly in the early summer, is extremely bright and pleasing, giving us perhaps the purest yellow we have in bedding Roses. It has, however, two very serious faults; the form of the flower is very poor, which makes it of little account for cutting, and the plant is sadly liable to dying back after the winter for no particularly obvious reason.

Souvenir de Gustave Prat is the fifth yellow Rose of this year I shall name, and is a pale sulphur-yellow with deeper centre. The buds are pretty and attractive, but the open flowers have no great interest.

A. Hill Gray (1911) was a great acquisition to our bedding Teas. It has good foliage, and a nicely formed lemon-yellow flower, occasionally large enough for the front row of an exhibition box, but its true place is rather among the decorative than exhibition Roses. Another little orange-yellow Rose of the same year is Herzogin Marie Antoinette. It is a nicely formed little flower, and one that has given me a good deal of pleasure, but the plant is rather a weakly grower, and so cannot be generally recommended. For those, however, who appreciate a small, nicely formed flower of particularly beautiful colouring, I would suggest that it is worth a trial in the way I grow it, namely, by leaving it practically unpruned. Being of bushy habit it will break from the base and never gets leggy. I always keep a few plants near my door for the pretty little button-hole flowers it produces. Melody, of the same year, is beautiful in colour under glass but uncertain in the open.

Cissie Easlea (1912) is a paler Rayon d'Or with very glossy foliage, and Marie Adelaide, of the same year, I look upon as a slightly fuller and better shaped Marie Antoinette, but it is somewhat troubled with black spot, and not quite so free as that little Rose: still it is worth growing. Sunburst, also 1912, is a good grower, and beautiful when it comes yellow, but the majority of the flowers are a dull white and uninteresting.

Mrs. Wemyss Quin (1914) is perhaps the greatest advance in the direction we are seeking that has yet arrived. It is quite a good garden Rose, with glossy foliage and good growth. The flowers are a rich golden-yellow and nicely formed, but never more than medium size, and therefore it is purely a decorative and bedding variety. It deserves to be more widely grown.

Lady Plymouth (1914) is very nearly a fine Tea Rose. It is a full flower, of good form, and large enough for exhibition: the foliage is excellent and the plant has a good constitution. It has, however, two defects which prevent it attaining the first rank. These are that the flowers are easily and seriously injured by rain, and the colour is a pale yellow suffused with buff, which gives it a slightly dull appearance.

Constance (1915) is a Rayon d'Or of slightly improved form, and I trust of rather better constitution. At least, it has not hitherto shown that unfortunate tendency to die back after the winter which I have noted as characterising Rayon d'Or.

Mme. Collette Martigny, of the same year, is a decorative Rose of the orange-yellow type, but has not grown very strongly with me as yet.

The Roses of later years are still on trial, and one cannot yet write of them with any assurance. The following are some that have been exhibited:

Shown in 1915.—Golden Spray, with arching stems about 3 feet long, covered with semi-single flowers.

Golden Emblem, a rather thin flower, of the Rayon d'Or colouring.

Joanna Bridge, a pretty and free-flowering plant, with thin, scarcely double flowers, canary and buff-yellow.

Tipperary, like Sunburst, has the orange-yellow colour in the centre, fading off to white at the edges. The plant is a good, strong grower, and the flowers are well shaped and fuller than Sunburst, but like that Rose, they appear to lose their colour as the season advances.

Shown in 1916.—Chrome is a name which describes the colour of its flowers, which are of fair form and medium size.

Lilian Moore, cadmium yellow, paling towards the edges, and as shown might be considered a fuller Mrs. Aaron Ward.

E. H. T. Broadwood has orange-yellow, nicely pointed flowers.

Christine, the brightest Rose of the year, has prettily-formed flowers of the decorative type, and a rich golden-yellow colour.

Shown in 1917.—Mrs. Redford, with coppery-orange flowers.

Shown in 1918.—Golden Ophelia was very finely shown early in the year as a beautifully formed golden-yellow flower of medium size.

Lamia, a pretty little decorative Rose, of the colouring of Mrs. A. R. Waddell, with brown stems and good foliage.

This concludes my list, from which it will be seen that a considerable amount of work has been done towards improving the yellow Rose, but the ideal, the hardy and dwarf Maréchal Niel, still escapes us.

It is rather curious, and perhaps illustrates the still primitive character of the yellow Rose, that such development as has proved practicable has taken place almost entirely along the lines of the decorative Roses. With the exception of Mme Mélanie Soupert, and very rarely with Souv. de P. Notting and Lady Plymouth, a Rose large and perfect enough for exhibition is not to be found, and Mme. Mélanie Soupert, beautiful as she is, is not pure yellow

Again in colour, though great advance towards the pure golden-yellow has been made, there has been a considerably greater production of the orange colouring. At one time it looked as though this golden yellow was to come through the Teas, but M. Pernet Ducher's introduction of the Persian Yellow has helped and enlarged the area of selection, with the result that there are already in the nursery beds and gardens many bright yellows, some of which, after preliminary trial and selection, may appear in public. We want, however, a fixed colour, which will not

deteriorate in autumn or cold weather, as does that of many an otherwise promising yellow Rose.

Of this decorative type I think I must regard Mrs. Wemyss Quin as the most generally satisfactory garden plant that has yet had any trial. Good foliage, good constitution, good form, good colour, and a free and constant supply of flowers. All these merits it has in greater or less degree. Christine should prove a graceful rival if it is found to possess these qualities when it comes to our shores from Ireland. In spite of the new blood it may quite well be that we shall have to go back to the old Maréchal Niel strain yet to get the full golden Rose. Mr. George Paul's Lemon Pillar was a Maréchal Niel cross, and though its shade of creamy-yellow excludes it from my list, yet it shows that a hardy and well-shaped Rose of the old strain is not beyond the powers of achievement. I can as yet detect no fragrance in the new yellows. *White Rose.*

NOTES FROM WARLEY PLACE.

CROCUS VERNUS.

"A South European and West Asiatic genus, a few species extending into Central Europe, and several long since cultivated for ornament and one for Saffron, collected from the stigmas, have established themselves in a few localities still farther north." Thus Bentham and Hooker, in *British Flora*. Hayward, in the *Botanist's Pocket Book*, gives Crocus vernus as V.R. (very rare) in pastures in Suffolk.

Hooker, in *Students' Flora*, states: "Naturalised in meadows."

Sowerby, in *English Botany*, thus refers to Crocus vernus:—"Completely naturalised in meadows in several places in England. Very abundant in Nottingham meadows, where it has been long known to occur; also at Murdham on the confines of Norfolk and Suffolk, and at Hornsey, Middlesex. In many other places it has been noticed, but only as the outcast of gardens. In Ireland it is plentiful near the Old Castle, Dunganstown, Wicklow."

It will thus be seen that Crocus vernus is only allowed a place in the British flora on sufferance, as it were: many botanists have wished it might be formally admitted, but it is still relegated to the alien camp.

To refer to earlier references to the Crocus we find that according to Turner (1551) and Gerard (1597), five or six species of Crocus were in cultivation in England at the end of the 16th century. Shakespeare often mentions Saffrons in his plays. In his time the name was in general use for all Croci, and even included Colchicum. It is not known if Shakespeare was acquainted with Turner and Gerard, but as they were contemporaries it is more than probable.

The Rev. Wolley Dod remembered the fields around Nottingham Castle purple with the Crocus, and there was no evidence of their having been planted there. He had been at some pains to trace their origin, or to discover a time when they had not existed, but without success.

Although Gibson, in his *Flora of Essex*, 1862, makes no reference to the Crocus at Warley Place, nor indeed does he refer to the genus as occurring at all in Essex, it is well known to have been growing here for many years. I have traced it as far back as 1620 or 1630, but I have not come across any record of its planting.

In the days before modern ideas invaded the countryside recreations of a much simpler nature pleased the villagers, and an event of the year was a visit to Warley Place when Crocus vernus was in flower. Many a farmer would lend his waggon for the day to convey a happy little party of mothers and children to see the purple fields of Crocus. I have noticed that the Lent Lilies have their years of beauty followed by a comparatively dull season, but with the Crocus the wealth of colour never lessens, although unpropitious weather will mar the blossoms and shorten the period of flowering.

Geographical forms of Crocus vernus show great variation in size and colour. I have collected a large series of these forms on the Continent. Even at Warley I have observed minor variations, and occasionally a flower where yellow predominates. Albinos are frequent. In *The Garden* of February 8, 1919, were some excellent views of the Crocus fields at Warley Place, which give a very good idea, but a naturally restricted one, and convey but a very limited impression of the beauteous scene when the long shadows of the Spanish Chestnut trees stretch across the undulating sheen of purple glistening in the spring sunshine. *E. Willmott.*

ORCHID NOTES AND GLEANINGS.

MACODES ROLLISSONII.

FOR many years, fifty or more, an Orchid has been in cultivation under the name of Goodyera Rollissonii. It was said to have been first distributed under this name by Messrs. Rollisson and Son, Tooting, in whose nursery it had appeared as a chance introduction, a kind of stowaway among other imports. The late Mr. Henry Boyle, who was a keen collector and cultivator of Anaectochiluses and allied Orchids, was of opinion that it was a hybrid, probably between Goodyera discolor and Anaectochilus Petola. Twenty years ago a plant of it flowered in Mr. Elwes' collection and Mr. Rolfe then identified it as a species of Macodes, distinct from all others known, and he renamed it Macodes Rollissonii. Such is the history of the plant, a good example of which, grown at Kew, is illustrated in fig. 34. Macodes is a Javanese genus, the two best known species being M. Petola and M. javanica; a third, of recent introduction, being M. Sanderiana. These orchids are remarkable in having fleshy leaves prettily marked with reticulating lines, their flowers being comparatively insignificant. Before the suffragettes destroyed nearly the whole collection of these pretty-leaved Orchids which for many years had been a feature at Kew, they were cultivated there with conspicuous success in pans covered with large bell glasses. A few kinds remain, but they only serve to remind us of the collection as it used to be. It may be observed that all the Orchids of this group appear to be monocarpic, as they invariably die after they flower.

CYPRIPEDIUM HERA EURYADES NEW HALL HEY VARIETY.

VARIETIES of this cross between C. Boxallii and C. Leeanum are numerous, and have played a very satisfactory part in the hands of the hybridist. The New Hall Hey Variety is one of the showiest in its normal form, but a very remarkable flower sent by William Bolton, Esq., Wilderspool, Warrington, which has two full-sized, perfectly-developed dorsal sepals diverging from the centre, on each side of the normal position of the sepal, represents it in a new light. The plant has produced similar flowers before. The two dorsal sepals are exactly alike, their bases are sap-green, and the other two-thirds pure white. The greenish base has dark maroon blotches, the white upper part but smaller rose-purple spots. The broad petals are spotted and lined with dark purple on a yellowish ground, the face of the lip being tinged with purple.

It is not uncommon to see extra segments in Orchid flowers, due usually to some abnormal torsion.

FORESTRY.

TREE PLANTING BY THE STATE.

Two of the original pioneers of afforestation in this country were the late Sir John Lubbock and Dr. Lyons. I can well remember discussing the question with Sir John on a Sunday afternoon in his beautiful woods at High Elms, when he decided to again approach Parliament on what he described as the momentous question of providing timber for the future and taking steps to promote the study of forestry in this country. A few days afterwards I mentioned the matter to Edward Henry Lord Derby, who, being an ardent arboriculturist, was much in favour of the proposed scheme, and told me to plant some of the waste land on his estate at Holwood, and on the newly-acquired properties of Leaves Green, and the Vale of Westerham. Shortly afterwards Sir John Lubbock persuaded the House of Commons to appoint a Select Committee to inquire into the best methods of developing British woodlands. This Committee's report, which strongly urged the study of forestry and the commercial aspect of tree-planting, was, however, shelved, and no direct action taken till 1902, when, in order to inquire fully into the matter, a Departmental Committee was formed, but with no better results. Dr. Lyons' scheme fared no better, when a Committee was appointed to consider the possibilities of tree-planting in Ireland. Nine years ago hopes of afforestation were high, when the Royal Commission on Coast Erosion issued its report, but again nothing was done.

Further than the planting of some ground at Knockmullen, in Ireland—which, by the way, was a complete failure and the purchase of a comparatively small area of land in Scotland for experimental purposes, little has been done by the State towards meeting our wants in the matter of an extensive and well-thought-out scheme of tree-planting.

Private individuals and public bodies have, so far as possible, assisted by the planting of estate lands and catchment areas, but this is about the sum total of our contribution to one of the most pressing and important of our national problems. It has been left to the war to bring home to the Government the urgent need of afforestation and the necessity for large and assured timber resources within its own boundaries.

With a life-long experience of British forestry, I have become more and more convinced that, in order to carry out the work and to place it on a systematic and sound economic footing, State aid and the afforestating of large areas of land are first necessities. There are few landowners or capitalists who would care to embark on a large scheme of afforestation from which they cannot expect to reap a return during their lifetime. While, for capital invested, a safe and sure return is guaranteed by many mining and other industrial companies that are financially safe, attention will be directed to these rather than to a project that is experimental, and from which there can be no return for thirty or forty years. The resources and continuity of a nation will always make the State the best custodian of forest property; indeed, only the State can readily acquire the necessary land on the most favourable terms and in sufficient area for the purpose of extensive afforestation. Private individuals, or, indeed, public bodies, labour under many disadvantages in that respect, not the least, as before stated, being the length of time required before the money expended in planting can be even partially repaid, while regularity of action and large wooded areas are first necessities to successful timber culture. The question of national reafforestation has on several occasions been exhaustively dealt with by the writer and others during the past thirty years. As early as 1883 I drew attention to the matter in *Woods and Forests*, and at later periods in most of the leading journals and papers of the day, including a special article to the *Field* and *The Gardeners' Chronicle*, while in my evidence given before the Select Committee on Forestry, and in a paper contributed by special request to the Board of Agriculture, I went fully into the question of afforesting, and pointed out the need for and saving to the country that would be effected by a well-organised scheme of tree-planting. In this connection I suggested that 1,000,000 acres should be planted over a period of twenty-five years, at the rate of 40,000 acres per year, which would be an outlay of £300,000 annually—a small sum when compared with the £25,000,000 expended for many years by this country on supplies obtained from abroad.

The Forestry Sub-Committee of Reconstruction has now reported that 1,180,000 acres are to be planted in the first forty years, which cannot be considered as an extravagant scheme, and is practically what I suggested twenty years ago and at several later dates since.

Mr. Lloyd George recently stated: "You also have forest lands which are unsuitable for higher cultivation. You have no idea how we were handicapped because we had to bring timber from Norway, Sweden, and Canada, when you had plenty of land in this country that in the old days used to grow fine timber." And the Sub-Committee rightly remarks: "Dependence on imported timber has proved a serious handicap on the conduct of the war." It also estimates that approximately 100,000 acres will require to be afforested with hardwoods in order to render the Kingdom safe during future wars. Owing to the long rotation necessary for hardwooded, over coniferous, trees, the planting of such must necessarily be carried out by the State, 150 to 200 years being nothing in the lifetime of an Oak or Elm. Restocking denuded areas, which are estimated at fully 1,000,000 acres, will mainly fall on the proprietors of these lands, and, owing to the enormous quantities of timber that have been removed from many estates, there will naturally be a tendency on the part of the owners not only to strictly conserve what is left, but restock the denuded areas as quickly as possible. It therefore stands to reason that private enterprise will be mainly expended on planting up cut-over woodlands and can do little in the afforestating of large areas of waste land, work which must be left entirely in the hands of the State.

Public bodies have in the past done excellent work in the planting of catchment areas of water-works and mine-heaps, but this is infinitesimal when compared with what is required.

At the commencement of the war we had, roughly speaking, 3,000,000 acres of woodlands, much of which required thinning, in addition to which the quantity of field and hedgerow timber proved a big and valuable asset. But, apart from this, we have been receiving consignments of mining timber from France, and had, when the war commenced, a fairly good stock in hand of foreign woods. It has been carefully computed that a million acres of woodland have been denuded for war purposes, while minor thinnings from small woods all over the country, and that from field and hedgerow, have been valuable additions in meeting the wants of the War Office during the past four years.

The greater proportion of heavy Elm, Ash, and a goodly supply of Oak, has been from field and hedgerow, while the whole of the coniferous timber, including Larch, Spruce and Scotch Pine, has been obtained from woods and plantations.

Beech and Sweet Chestnut have been supplied from such well-known centres as the Chiltern Hills, and from large private properties like Welbeck and Woburn. It was prophesied by some wiseacres at the beginning of the war that our available supplies of timber would be exhausted in two years. Such, however, has not been the case, and at our present rate of consumption it is calculated by those who have studied the question that there is still sufficient left to last for another two years. The afforesting, therefore, of a million acres of waste land and the replanting of the denuded areas will leave us with fully 4,000,000 acres of woodlands. No time should, however, be lost in setting to work, remembering that no scheme of afforesting, however extensive or well-ordered, can bring the necessary relief for at least forty years after it is commenced. *A. D. Webster.*

FIG. 35.—ARTEMISIA JUDAICA AT BELVOIR CASTLE.

(*See page 95.*)

THE FOOD OF WORMS.

(*Concluded from page* 37).

All the evidence goes to show that earthworms live largely on vegetable matter, mixed with earth and small stones, but that they are not averse from animal food, and may even be guilty of cannibalism. Those who assert that the bulk or the whole of their diet is composed of amoebae of the soil mostly do so on the strength of assumption. But assumption is not proof. How, then, did the amoeba theory arise? On what grounds is it based? It might arise from the fact that recent research proves the existence of large numbers of amoebae in the soil. Since worms live in the soil, what more natural than that they should live on these things? Recent investigations have further shown that worms are infested with a wonderful variety of parasites, and since the subject has hitherto been but indifferently investigated, casual observation might lead one to conclude that the parasites were really the food on which the worms had been feasting.

Now this topic of parasites is a very extensive as well as a most important one for many reasons, but it must be reserved for later treatment. It is enough to suggest this possible connection and set it aside as inadequate. To demonstrate that earthworms feed on amoebae would involve a series of carefully conducted experiments, and it is perhaps not too much to assert that they would end in failure. But there again assumption comes in. How can such an assumption be justified?

Think of the microscopic character of the creatures on which the worms, according to the amoeba theory, have to subsist. None but students working with powerful microscopes ever see them. The popular idea of amoebae is based on the largely magnified representations of them found in text books and popular natural histories. They are in reality invisible to the naked eye.

But it might be replied, "When we speak of amoebae we use the term vaguely to include all kinds of organisms found in the soil. Such terms as 'worm' and 'insect' are often employed in such a popular sense; and if worms have the whole of the minute life of the soil for their larder, may they not reasonably be supposed to have a very good time of it?"

This opens up a very big question, because of the issues it involves. If worms feed on the minute animalculae found in the soil—amoebae, protozoa, bacilli, bacteria, or what you will—do they digest them? Can they feed on them, and yet pass them alive into their "casts"? Evidently not, for that would be an abuse of terms. When living matter has been used for food, only dead matter passes out at the vent. Hence we find ourself facing topics of the highest importance. If worms digested germs they would be our most valuable scavengers. But what do we find? Let us turn to the researches of Pasteur for an answer.

This famous French savant was studying splenic fever. After the dead cattle had been buried, did the germs of the splenic fever return to the surface of the soil? If so, by what means? The eager student is ever on the alert for clues, and one day the answer to the enigma suddenly presented itself. Passing through a field which had recently been cropped, Pasteur observed a patch of ground where the soil differed in colour from that which adjoined it. On inquiry he learned from the proprietor that sheep which had died of anthrax had been buried there the preceding year. Drawing nearer, Pasteur observed a number of little twists of earth or worm-casts. Might not these afford the explanation? Was it possible that the worms, returning from their subterranean journeys in search of food, brought back the germs? Could these harmless creatures by any means feed on the dead carcases; or, if not, did they swallow the soil which might become impregnated by contact with the dead, and so act as the media of transmission? Would such germs, if taken into the worm's body, be assimilated and destroyed; would they resist the action of the pharynx and gizzard and digestive juices (containing pectic, diastatic, and tryptic ferments), and come out alive; and finally, if voided again, would the disease germs be active? If active, would their action be lessened, remain normal, or show signs of intensification? Here were all-important problems to solve. He at once put the matter to the test. His assistants collected worms from the affected area, and, to quote the words of the original, "anthrax spores were found in the earth cylinders which filled their intestinal tube" or stomach.

Pasteur was ever thorough in his work. He therefore went further, and by examining earth from the pits where cows which had perished from splenic fever had been buried he found that it contained the spores of the disease. The rich humus of these mounds produces fresh and juicy grass upon which the cattle fed greedily. But when showers come the worm-casts disappear, the germs contained in them are liberated, and thus get mixed with the pasture. For which reason, as Pasteur urged, animals should never be buried in places where cattle feed.

The subject may be approached in the next place by the exactly opposite avenue. We have seen the results of examining worms which have fed in soil rich in germs; now let us take the leaf-mould on which they usually subsist and sterilise it. If the nutriment which sustains them is of animal origin, sterilisation will remove it, and the worms cease to flourish. I had occasion recently to put this matter to the test. The point was to discover the action, for good or ill, of worms on living plants. That there might be no question of other living organisms doing the work, the soil was first sterilised and the worms afterwards introduced. Yet, though the leaf-mould and earthy matter were destitute of living germs, the worms continued to flourish.

For a long time there has been a dominant theory that worms of various kinds may be regarded as the enemies of living plants. It has been affirmed that they will attack the roots or other parts of Asters, Primulas, and other flowers, Clover and grasses, and even more woody growths. That is hardly what one would expect from creatures which find their chief sustenance in tiny, jelly-like animalculae. Granted the argument is not supported in the sense in which it has usually been advanced, it is nevertheless true that worms (as Darwin observes) can find nutriment in living plant tissues, and are frequently found doing the work of camp-followers among various kinds of plants which have begun to weaken from various causes.

One more fact may be adduced in conclusion. Earthworms have many relatives. There are the larger forms found in tropical and other lands. These are known to feed on soil and decaying humus or vegetable matter. Many native species abound in strong manure where amoebae are not found in sufficient numbers to be of use for food. Small white worms (Enchytraeids) and water-worms (Tubificids, etc) abound in every suitable locality in these islands. I have studied very many thousands in a living condition under the microscope, have watched them taking their food, have examined their parasites, analysed their faeces and the contents of their stomachs, and yet have never once succeeded in finding amoebae there.

The answer seems to be clear. Worms do not subsist on animal organisms found in the soil, but on the nutriment to be derived from vegetable matter, preferably decaying leaves, humus, and manure. *Hilderic Friend.*

VIOLET CYCLOPS.

The very pretty new variety of Viola odorata figured in *The Gardeners' Chronicle* for November 16, 1918, under the name of Mrs. David Lloyd George recalls strongly—especially by the presence in the centre of the flower of four little supplementary petals, forming a sort of "eye," of a lighter colour—a similar variety obtained in France about 15 years ago, and placed in commerce by Messrs. Vilmorin in 1916 under the name of Viola odorata cyclops. This variety, which is described in the 5th edition of *Fleurs de Pleine Terre*, by Vilmorin, has never been very well known, and is hardly now to be found except in a few collections, and in the nurseries of certain horticultural specialists. *A.M.*

ARTEMISIA JUDAICA.

Because of its graceful habit and the silvery whiteness of its foliage, Artemisia judaica is a very suitable subject for use as a "dot" plant in the flower gardens during summer. If seeds are sown early in March in a warm house, good plants may be obtained for planting out of doors in May. These may be lifted in the autumn if large specimens are desired the following season, and they should be grown in a temperature of 40° to 45° during the winter. The illustration in fig 35 represents a plant that survived a mild winter, unprotected, at Belvoir Castle, and became a large specimen the following season. It occupied a dry border facing south, and was much admired *W. H. Divers, V.M.H., Westdean, Hook, nr. Surbiton.*

THE ALPINE GARDEN.

WINTER-FLOWERING ALPINES.

So far as I know, there are only two rockery plants which flower exclusively in winter, and which, in such a winter as we had 12 months ago, will keep up a brilliant display from October to March. Cyclamens and Ceratostigma Griffithii linger on till Christmas; Erica carnea, Iris unguicularis, and sometimes Adonis amurensis, are in flower before New Year's Day; but nothing in these late and early growths covers the whole six months. The first of the two plants which manage the business is Lithospermum rosmarinifolium. It is astonishing that this glorious Alpine should be so little grown. The flowers are rather larger than those of L. prostratum, and of quite as fine a blue. People are probably deterred from tackling it by finding it described as tender. Tender it certainly is. A bad frost will always kill it. But I have known plants, on the rockery here, survive three winters in succession. It is wisest to reckon that the plant will be lost in the New Year, and to lay plans accordingly. The following procedure works well:—Take cuttings in July. They strike very readily, and in August may be potted into 3-inch pots. Keep these little plants under glass through the winter. They will bloom at once and be very delightful. In April, turn them out of the pots, and put half the stock in a sunny position on the rockery. They will grow rapidly, and from September onwards will steadily increase in beauty, while everything about them is dying down. Keep the other half of the stock as a reserve, but do not pot at once into larger pots. The result, here, at any rate, is that the plants soon become pot-bound. Plant them out in a frame, or a sunny bed. In early autumn lift and pot them. Under glass they will be glorious all through the winter, and will provide an ample stock of cuttings for July. Kew might do worse than give its winter visitors an object-lesson in what can be done with this very easily managed plant.

The second "all-winter" plant, which flourishes on my rockery, is Euphorbia biglandulosa. It is handsome at all times, with its 18-inch stems and glaucous green leaves. Like the Lithospermum, it begins to flower in early autumn, and continues in bloom till spring. Hard frost harms it to the extent of laying the flowering stalks on the ground, and so spoiling the plant's beauty. But the stock is thoroughly hardy, and the new shoots come up vigorously in spring. I will not say that it is as showy as E. epithymoides, but it is not much inferior in beauty.

I wonder whether some kind person can put me right about Colchicum montanum. Here it is about the earliest of the spring flowers, and has generally faded away before the Eranthis begins. But many years ago I used to have it in the form of a small white flower. Now bulbs under its name produce a larger flower, with a faint touch of the odious Colchicum red. To anyone who doesn't mind this red—not at all faint—or who will tolerate it for its striking effect, I recommend Colchicum hydrophilum. It is a good, hardy perennial, flowering in January, and producing showy, though small, flowers, of a truly atrocious magenta. *A. K. Bulley, Neston, Cheshire.*

TANAKAEA RADICANS.

TANAKAEA is a monotypic genus belonging to the natural order Saxifragaceae, and closely allied to Rodgersia and Astilbe. T. radicans (see fig. 36) is an evergreen, tufted plant, growing about 6 inches high, with leathery, oval leaves on long, slender petioles. The inconspicuous greenish-white flowers are produced in panicles like those of an Astilbe, but on a smaller scale. The plant spreads by means of runners, which produce young plants like the Strawberry. It is essentially a woodland subject, requiring a shady position in rich soil with plenty of decayed leaves. In the rock garden a shady corner in a sheltered bay may be found in which it will flourish. Although not an attractive plant from a garden point of view, its evergreen character makes it quite worthy a place where interesting, apart from showy, plants are cultivated. When exhibited at one of the meetings of the Royal Horticultural Society in 1903, the species obtained the award of a Botanical Certificate. It was introduced into this country from Japan by Mr. W. H. Stansfield, of Southport, in the year 1899, and is figured in *Bot. Mag.*, t. 7,943, *W.I.*

FIG. 36.—TANAKAEA RADICANS: FLOWERS GREENISH-WHITE.

A VETERAN GARDENER.

THE following note appeared in the *Hobart Mercury*, December 2, 1918:—

"Mr. William Smith, who was born in Devonshire on March 14, 1812, died last week at the Old Colonists' Homes, North Fitzroy (Vic.). Although nearly 107 years of age, the old man had only been in the homes about two months, having prior to that period supported himself as a gardener. He was wonderfully active and alert for his age. He came to Australia in the ship 'Rattlesnake' in 1883, and was a member of a party sent out by the British Government to make botanical and geological inquiries and surveys. He was well known as a gardener in the Western district, having worked at Tahara, Mt. Talbot, and other stations."

Assuming the newspaper account to be correct, Mr. Smith would almost certainly have been at the Royal Botanic Gardens, Kew, or recommended by Kew, but I do not remember ever hearing of him there. He would be the doyen of the Botanical profession, and, while clergymen are supposed to hold pride of place for longevity, I doubt if there is one still in harness at 106. *Arthur Garnett, Cambridge, Tasmania.*

The Week's Work.

THE KITCHEN GARDEN.

By G. ELLWOOD, Gardener to W. H. MYERS, Esq., Swanmore Park, Bishop's Waltham, Hampshire.

Marrows.—Early Marrows are greatly appreciated, and seeds sown singly in 60-sized pots now will furnish plants for early cropping. Germinate the seeds in a house or pit having a temperature of 60°. Transfer the seedlings to larger pots or boxes as they need increased root room, planting them eventually in a compost consisting of equal parts loam and manure from a spent mushroom-bed, with a little leaf-mould and mortar rubble added, on a mild hotbed. Some of the plants may be placed in large pots and trained to a trellis in vacant places in a house having an intermediate temperature. Pen-y-byd, Epicure, and Table Dainty are three excellent varieties for early cropping. It is an advantage to pollenate the flowers when they are opened fully, to ensure the fruits setting.

Brussel Sprouts.—The Brussel Sprout requires a long season of growth to produce large and early sprouts, and the present is a suitable time to make the first sowing. Sow in boxes filled with sandy soil, just cover the seed, and place the boxes in gentle warmth. When the seedlings are large enough to handle, prick them off into other boxes at three inches apart. When well established, harden them gradually, ready for planting out of doors in April. Sutton's Dwarf Gem is a splendid early variety.

Potatos.—To maintain a regular supply of tubers for use, well-sprouted sets of an early variety should be planted in pits, or on a hotbed furnishing steady warmth. Plant the "seed" tubers in rows at 18 inches apart and 4 inches in depth. Keep the light closed until the top growth appears, and be prepared for frosts by having covering material at hand.

Broad Beans.—Good breadths of Broad Beans should be sown from this date onwards, for plants raised from seed sown now produce the heaviest crops. The ground for Broad Beans should have been previously well prepared by manuring and trenching. Sow the seeds in rows made 30 inches apart, placing them alternately in the drills at a distance of 7 inches. When the plants are 8 inches high, earth them up. Hoe the soil on frequent occasions. A single row of Spinach or Turnip may, with advantage, be sown between each row of Beans as a catch-crop.

Cauliflowers.—The present is the most opportune time to sow the finer varieties of Cauliflowers. The plants should grow steadily without a check for a long period. Sow the seeds in boxes filled with sandy soil made firm, and germinate the seeds in very little warmth. When two true leaves are well developed, transfer the plants to boxes, putting them 3 inches apart. Some of the seedlings may be pricked out in cold frames, at the same distance. Keep the frame closed for a few days, until the roots are established. Water and syringe the seedlings with extra care, and admit air on all favourable occasions. Early Giant, Autumn Giant, and Autumn Mammoth will furnish a succession of heads, until the later sown varieties turn in.

Herbs.—The perennial kinds of Herbs should be dug up and divided, placing healthy portions in well-cultivated ground containing grit.

THE HARDY FRUIT GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

Raspberries.—The planting of Raspberries should be completed at the first opportunity. This small fruit has deep-growing roots, and forms numerous fibrous roots near the surface. The ground for planting should be trenched two spits deep and enriched with plenty of farmyard manure, leaf-mould, vegetable refuse and, where they can be had, ½-inch bones. Most kinds of soil suit the Raspberry, but heavy ground should be well drained and lightened with burnt garden refuse. Select strong, vigorous canes for planting, and cut away all damaged parts. In planting, place fine, rich soil about the roots and break up the lumpy portions of earth, as rough soils do not hold moisture freely in summer. Do not plant the roots deeply. Most varieties need some kind of support, and the best method is to train the canes on a trellis-work, which, for strong-growing varieties, should be placed 6 feet apart and the plants 2 to 3 feet asunder. Less vigorous varieties may be grown in rows 5 feet apart. The rows should run north to south. Raspberries planted now should be cut back to within 1 foot of the ground level, and weak ones to 6 inches, in February. It is much better to shorten the plants in this way, as canes which are allowed to crop the first year rarely make good shoots for fruiting the following season. Directly after planting place a mulch of short manure over the roots.

Autumn-Fruiting Raspberries.—This type of Raspberry requires a different treatment to that afforded the summer-fruiting kind, as the fruits develop chiefly on the tops of the young growths. All the old canes should be severed close to the ground in February; the stools will then make strong growths in the spring, and these should be thinned to about 15 inches apart, and not topped, as they do not need support.

Enemies of the Raspberry.—Raspberries are subject to the attacks of various insects, chiefly mites and weevils. Mites appear in spring, the lower buds being attacked first. All buds attacked should be picked off and burnt. In the case of bad attacks it is best to cut the canes down to the ground in autumn. Weevils are rather difficult to deal with; the best plan is to pick off all infested buds. Another plan is to shake the canes after dusk over a tray smeared with some sticky substance.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Lt. Col. Sir G. L. HOLFORD, K.C.V.O., C.I.E., Westonbirt, Gloucestershire.

Vanda, Aerides, and allied Genera.—Many well-known species of Vanda, Aërides, Angraecum, and Saccolabium are now showing signs of renewed activity, after having been at rest since last autumn. The plants should, as soon as the roots are active, be afforded fresh rooting-material. Healthy plants furnished with leaves

down to the surface of the compost should have all the old material removed carefully, washing the soil from amongst their roots without detaching them from the pots. After cutting away all decayed roots, arrange the sound ones amongst the fresh rooting-material, covering as many as possible of the aërial-roots at the same time. See that the drainage is perfect. The compost should consist of equal parts of A1 fibre and clean Sphagnum-moss, with a liberal quantity of broken crocks and charcoal. Surface the pot with fresh Sphagnum-moss trimmed neatly. Plants that have become unsightly through the loss of their lower leaves should be carefully taken out of their pots, and have sufficient of the lower portion of the stem removed, so that when the plant is repotted the lower leaves will be brought down to the level of the rim of the pot. The loss of the lower leaves is perhaps the most troublesome detail in the cultivation of these orchids. Growing a plant is only one part of the business; to conserve the foliage over any considerable length of time is another, and often the most difficult. The cultivator should provide an atmosphere sufficiently warm to ensure free growth, and allow sufficient sunlight and air to consolidate the growth at the later stages. When this is done, the plants will be in a condition to endure such slight checks as are bound to occur during winter even under the best of treatment. A position in the warmest house is usually recommended for these Orchids, but the majority of them will often grow equally as well in the intermediate division. The larger species should be grown on the stage, while the smaller kinds may be hung from the roof-rafters. These epiphytes require to be kept fairly moist at the roots all the year round, but as evaporation of moisture is slow in winter, much less water is required at that period than during the longer days when the plants are growing actively.

Vanda coerulea.—This species is, perhaps, the most popular member of the genus, the pleasing blue blossoms giving it a distinct and fascinating character. Like many others of the genus it is a free-blooming, healthy-growing plant under proper treatment, but, unfortunately, it is often seen in conditions wherein it cannot possibly succeed: for example, it will not be satisfactory for long in a shady, moist house kept warm and stuffy. I find the plants thrive better in a temperature one would term cool intermediate; solar heat they enjoy, but what they like most is a cool night temperature to recoup their energies after the heat of the day is over. Thus treated, the growth is firmer than that produced under hot, close conditions, and the leaves are not so liable to spot; for the same reason, the flowers have more substance and are of better colour. The pretty species, V. Kimballiana, V. Watsonii, Aërides japonicum and A. Vandarum, should be be afforded similar treatment.

FRUITS UNDER GLASS.

By W. Messenger, Gardener to C. H. Berners, Esq., Wolverstone Park Gardens, Ipswich.

The Orchard House.—The advantages of an orchard house for the production of first-class dessert fruits, where there is a difficulty in meeting the demand from out-door sources, is generally recognised. Although the conditions are conducive to an earlier ripening of the fruits, the aim is really to protect fruits from injury during inclement weather without any serious attempt at forcing. The house should now be made ready to receive pot trees which have been plunged in ashes in the open. The necessary work of pruning, cleansing, and re-potting carried out during the autumn obviates further work beyond the necessary one of clearing the ashes from the soil and pots. As the trees are removed to the orchard house, see that they are quite firm in their pots, and, if worms are present in the soil, use lime water to clear them out. If the trees are planted in the house, and it is intended to plant fresh specimens, the work should be done forthwith. Trees carefully lifted from the reserve ground will hardly feel a check, and should produce a satisfactory crop of fruit the following summer, under proper management. If not already done, the trees should be pruned and sprayed, the structure thoroughly cleansed, and the borders put in order. If the house is unheated, air should be admitted freely whenever possible, with the object of retarding growth: in any case, forcing should be gradual at the commencement, because if unduly hastened both flowers and growth will be weak and unsatisfactory. It will be beneficial if the trees are lightly syringed occasionally on fine days.

Figs.—Pot fig trees that have been subjected to a steady bottom-heat of 75° to 80°, will, in most cases, have fully developed their foliage, and the embryo fruits should be swelling freely. As the days lengthen and there is increased sunlight, more moisture should be afforded by frequently damping the house. Remove all superfluous and ill-shaped fruits from healthy trees, and see that the roots are never allowed to become excessively dry, otherwise there will be a danger of the fruits dropping prematurely. Pinch the shoots at the fourth or fifth leaf to guard against overcrowding. The disbudding, stopping, and training of the earliest established trees will now claim attention. Do not retain more growths than can be fully exposed to the sun and light, and train these into position at an early stage. Stopping should be done gradually, otherwise the second crop will follow too closely after the first and check full development of the early fruits. Strong growths may be stopped at the eighth leaf, and medium shoots at the fifth or sixth joint. Weak growths when not required to fill blank spaces should be removed, as it is from strong, close-jointed wood the finest fruits are obtained. Liberal supplies of liquid and artificial manures may be given to pot trees and those in shallow borders, but guard against encouraging gross growth, which is not conducive to fruit production. Successional trees should be kept dormant for another month.

PLANTS UNDER GLASS.

By James Whytock, Gardener to the Duke of Buccleuch, Dalkeith Palace, Midlothian.

Fuchsia.—Fuchsias and other similar plants, useful for decorating the conservatory during summer, and which have been at rest during the winter, should be started in a warm house. After they have made a little growth shake most of the soil from the roots, and pot them in small pots, after repotting them into larger pots as necessary. Fresh loam, mixed with decayed manure and sand, make an excellent compost. Fuchsia cuttings, rooted last autumn, may now be potted again and they will soon be ready for their flowering pots. Cuttings rooted now will make serviceable flowering plants by the autumn.

Bouvardia.—Where Bouvardias were rested and pruned after flowering it is desirable to cleanse the plants with an insecticide at this stage and place them in a warm house near the roof glass. When they have started into growth, shake the old soil from the roots, and repot them in a mixture of fresh fibrous loam, leaf-mould and sand. Syringe them daily, and to encourage good growth keep them near the roof glass. Young stock can be raised from root cuttings placed in a shallow pan of light soil, and plunged in bottom heat.

Canna.—Divide the old stools that have been at rest during winter, pot the separated portions in 6 or 7-inch pots, in rich loam, mixed with decayed manure. They do best if plunged in a bed giving a mild bottom heat, until growth is well developed, then remove them to the flowering house or conservatory.

Hydrangea. — According to requirements Hydrangeas should either be repotted, or top dressed with good loam and a little plant fertiliser. Place them near the glass roof in a temperature of 50° to 55°. When good growth results water frequently with liquid manure.

Ferns.—The present is a good time to repot ferns. Adiantums for decorative purposes are best grown in 6 or 7-inch pots. The pots should be thoroughly cleaned and well drained. To increase the stock, divide the old plants, pot them and place them in a moist warm atmosphere and shade from bright sunshine. It is not necessary to repot all ferns every year, as a top dressing of fresh loam and fertiliser, will suffice in many cases, but when in full growth such plants should be watered occasionally with a weak solution of sulphate of ammonia.

Asparagus Sprengeri.—Seeds of this useful decorative plant should be sown in pans plunged in bottom heat, and when fit to handle the seedlings should be placed in small pots, and afterwards several plants may be put in a large basket filled with good loam, leaf-mould, and rough material to keep the soil open; will make good in the autumn. Asparagus plumosus and Smilax are two most useful plants. Seeds germinate readily in pans in bottom heat. Pot the seedlings into 4-inch pots, and place them near the glass roof. When established in these pots they are most serviceable for planting against the back wall of a vinery or Peach house in a narrow prepared border in good loam and sand.

THE FLOWER GARDEN.

By H. Markham, Gardener to the Earl of Strafford, Wrotham Park, Barnet, Hertfordshire.

Climbing Roses.—Roses trained on poles and those clothing arches, fences and pergolas should receive attention before the young growth is far advanced. Where the plants were properly thinned last autumn very little further attention will be required beyond shortening some of the flowering shoots, cutting out unripened wood, pricking up the soil over and about the roots and affording a good dressing of suitable manure. Climbing Roses which have not yet received attention should have the older growths thinned out, and last year's growths trained into position without overcrowding. Aim at keeping the poles and fences covered with strong, healthy growths which will yield good clusters of bold flowers. See that all the fastenings are made good and do not cut the bark. There is still time to plant Roses.

Delphinium.—There is still time to increase the stock of Delphiniums by division. The outside growths, with roots and soil attached, are the most suitable portions to plant in soil well enriched with manure. Allow ample room for development. Seeds may be sown in pans of light soil placed in gentle warmth. Seedlings so raised will make useful plants much earlier than those raised out of doors in April.

Herbaceous Phloxes.—For the production of large heads of bloom, young healthy plants of Phloxes are needed. The outer portions of a clump should be lifted and planted in rich soil and supplied in summer with liquid manure at intervals. If stock is scarce quite small pieces may be rooted under glass

Lawns.—In many cases lawns have been much neglected during the past four years and they should now be put in order. In favourable weather sweep and roll the grass; then rake out all the rubbish and dress the lawn with a good fertiliser. If a good dressing of fine soil, free from small stones, can be given after the application of a fertiliser, it will soon be washed down to the roots and greatly assist the grass to grow. Roll freely and mow with a scythe before using a lawn mower.

Verbena and Salvia.—A good stock of Verbenas and Salvias may be raised from seeds sown at the present time. Sow the seed thinly in well-drained pans filled moderately firmly with sandy soil. A sheet of glass placed over the pans will help to keep the soil in a sufficiently moist state for several days, but the glass should be removed gradually after the seedlings appear. Verbena venosa makes a capital plant for massing, and may be raised from seeds or from cuttings which spring from the base of last year's plants, is started in gentle warmth, and similar treatment may be given Salvia patens.

General Work.—During weather unfavourable for outside operations, lawn mowers should be thoroughly cleaned and oiled, and any requiring repairs should be sent to the proper quarters to be put in order. Flower stakes, pegs, and labels usually required during summer time should be cleaned, pointed, and tied up in bundles in their different sizes.

EDITORIAL NOTICE.

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

APPOINTMENTS FOR MARCH.

SATURDAY, MARCH 1—
Bolton Hort. and Chrys. Soc. meet.
THURSDAY, MARCH 6—
Manchester and N. of England Orchid Soc. meet.
MONDAY, MARCH 10—
United Hort. Ben. and Prov. Soc. Ann. meet. at Roy. Hort. Soc. Hall. Bath Gard. Soc. meet.
TUESDAY, MARCH 11—
Roy. Hort. Soc. Coms. meet: Open class for early flowering bulbs in pots. Lecture by Mr. James Whitton at 3 p.m. on "The Glasgow Public Parks."
WEDNESDAY, MARCH 12—
Wargrave Gard. Soc. meet.
TUESDAY, MARCH 18—
Eastbourne Hort. Soc. meet. and lecture.
THURSDAY, MARCH 20—
Manchester and N. of England Orchid Soc. meet.
SATURDAY, MARCH 22—
Brighton Hort. Soc. meet.
TUESDAY, MARCH 25—
Roy. Hort. Soc. Coms. meet.: Lecture by Mr. Edward White at 3 p.m. on "The Study of Economic Botany and the Professional Openings it Offers."
WEDNESDAY, MARCH 26—
Wargrave Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.8°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday, February* 26, 10 a.m.: Bar. 29.5; temp. 43°.

Wart Disease of Potatos. All who have followed the spread — slow but implacable — of Wart Disease in this country are aware that this disease is becoming a serious menace to Potato growing.

It is true that, thanks to the work done by the Board of Agriculture, varieties resistant to this disease have been discovered, and that, contrary to the opinion often expressed by growers, some of the resistant forms are excellent croppers.

Records already published, and those of the Ormskirk trials about to be published, provide ample evidence of this fact. Furthermore, thanks to the enterprise of the raiser of new varieties, there is reason to hope that in the near future a larger number of resistant earlies will be available than is at present the case. So far, therefore, as Potato growing in this country is concerned, it is not unreasonable to expect that, should the disease continue to spread—as it certainly will—growers will have at their disposal a number of resistant varieties sufficient to enable them to select sorts as prolific and as suitable to conditions of soil and climate as are susceptible varieties. But this—satisfactory though it be up to a certain point—by no means disposes of the danger which is to be apprehended from this malignant disease. The nature of this danger may be judged from the following facts: No remedy for Wart Disease is known. The spores of the parasite which causes Wart Disease of Potatos are disseminated in the soil from tubers attacked by the disease. Hence they may be carried by any chance or routine practice which leads to the distribution of particles of soil. For example, they may be, and are, carried on the boots and implements of farm or allotment workers. A case is on record which illustrates this fact strikingly. An outbreak of Wart Disease occurred on a farm. One of the workers on the farm had an allotment and on that allotment Wart Disease had already occurred. It is not to be doubted but that the spores were carried by the allotment holder to the farm. The spores may be carried on ware Potatos and hence, if the latter are used for seed, soil infection may occur; or even if the peelings find their way through the pig-stye to the soil the disease may be spread.

Seedlings—as for example those of the Cabbage tribe—raised on infected soil have been proved to be a means of spreading the disease; for the spores are carried in the ball of earth attached to the roots of the seedlings and are sown when the seedlings are planted. Similarly, sacks used for the carriage of Potatos grown on infected land, if used again, may communicate the disease to seed Potatos destined to be grown on uninfected soil and hence cause infection of that soil. It cannot be too plainly understood that a resistant Potato may *carry* the spores of the disease just as readily as a susceptible Potato, and there is no doubt but that the recent spread of the disease is in part due to a lack of appreciation of that fact.

Furthermore, the spores of the Wart Disease are capable of remaining dormant for many years in the soil so that there is no hope of eradicating the disease by adopting a rotation. Nor, as it seems to us, is the palliative—recently advocated by Mr. Salmon—of sowing germ-infected land with grass, likely to prove of any value. "Il faut tout montrer pour tout guérir." Even buried under grass, the spores would rise to the surface—in the casts of worms and serve as means of infection, as was proved to be the case in the classical investigation of Anthrax by Louis Pasteur, referred to by the Rev. Hilderic Friend on p. 95.

The foregoing facts show that the menace of Wart Disease is a very real one. So far as Potato growing in this country is concerned, the menace may be circumvented by planting immune varities, but—and here we come to the most serious part of the case—this method of circumventing the disease will still leave immune seed grown in infected areas its powers of carrying infection. Now it is beginning to be widely known that Scotch and Irish seed is the best in the world, and there should be great possibilities of a large increase in the export trade of seed. It is therefore vital to the industry that means be found to ensure that all seed and ware grown in infected areas shall be consumed in this country, and that only ware and seed grown in uninfected ground shall be exported. Such a suggestion would possibly be rejected by growers generally, who, for reasons with which we can sympathise, wish to throw off the uncomfortable yoke of State control; but anyone who will review dispassionately the facts of the situation will reach the conclusion that Potato growers and merchants must take this subject up without delay, consider it carefully and either acquiesce in a control of Potato distribution, or devise some other means of safeguarding their ultimate interests.

In the meantime it will be evident that the most alert and constant inspection must be maintained. The widest possible publicity must be given both to the symptoms and dangers of Wart Disease. Research must be undertaken with the object of discovering means of soil sterilisation, so that at all events local and circumscribed outbreaks may be checked. The source of origin of seed must be watched and every means taken to prevent the planting of seed from suspect places.

Hampton Court Gardens. The furore raised by a proposal to make certain alterations in the gardens at Hampton Court reveals how strong is the affection among the people for that popular place of public resort. The control and management of the gardens, like that of the Royal Parks of London, are vested in the Office of Works, Major Hussey officiating as bailiff. Incidentally we may mention that Kew Gardens were under the same control till 1903, when they were transferred to the Board of Agriculture.

Hampton Court owes its popularity as much to its historical associations as to its many attractions. From the time of Henry VIII, when the magnificent Cardinal Wolsey built the palace and surrounded it with gardens and park, Hampton Court, as a residence of kings, and as a place of "many beautiful gardens," planned and maintained at great cost by the most eminent gardeners, has been world famous. Charles II, who loved planting and building, did much towards fashioning both park and gardens as they are to-day. He sought the advice of the famous Le Nôtre, evidences of whose taste are seen in the avenues, vistas, and the use of water. William and Mary did much towards perfecting the original plans, assisted by Rose, London and Wise, three of the most eminent gardeners of that period.

George III was the last English Sovereign to reside at Hampton Court, and Queen Victoria made both palace and gardens over to the public, by whom they have continued to this day to be greatly appreciated, as much for their rich displays of spring and summer flowers as for their more permanent features.

When "Capability" Brown, whose work in the latter half of the 18th century, as a renovator of old gardens and a designer of new, did a great deal for the creation of what is now known as the English style in landscape gardening, was desired by George II to improve Hampton Court Gardens, he declined, "out of respect to himself and his profession."

There are no doubt, many who take an interest in gardening who would not hesitate to make changes at Hampton Court. The summer bedding, immensely popular though it is, has its detractors, who would abolish it altogether. Whether it is good taste or the reverse to have rich displays of flowers in beds more or less formal, depends on what the canons of good taste are. In music, painting and architecture, we please ourselves, or ought to, but when the public are concerned we must please them, or they have a right to complain. We might with as much reason change the tune of the National Anthem to one of real Wagnerian strain, as change the flower gardening at Hampton Court. Let us, therefore, continue to have our great feasts of Flora's wealth there, leaving the quieter, "dignified" efforts to the parks adjoining.

Owing to the war, the flower beds at Hampton Court were turfed over, and the

houses and frames in which the summer bedding plants were nursed, were devoted to Tomatos. There is no longer any need for economies of this kind. No doubt when the flower beds are remade it will be possible to improve on the old plan, but there should be provision for a great display as in pre-war times. The proposal to widen the borders for herbaceous perennials by taking in a strip of the broad walk is commendable we think; at any rate, the grass verge in front of the borders should be wider; six feet would not be too much.

The Dutch Garden certainly does require attention. It has ceased to be "Dutch," owing to the ragged and generally worthless character of the mixture of shrubs and small trees which occupy the beds. In our opinion this garden should be restored to what it was intended to be. This could be done at little expense, by replacing the nondescript shrubs with suitable evergreens, such as Berberis, Rhododendron, Erica, Olearia, Pieris, Rosmarinus, Cotoneaster, Daphne, Euonymus, Skimmia, Ruscus and others. Each bed should contain only one kind of shrub, kept fairly uniform in height. Lilies, Paeonies and Daffodils could be dotted planted among the shrubs. The grass paths should be widened. It will be seen that these suggestions are for restoration and not alteration, to which the public have a right to object.

With regard to the removal of certain trees in what is called the "Wilderness," we are very decidedly of opinion that improvement is called for there. The noble Lion Gates are demeaned by a wretched tea garden just outside them, and immediately inside there are only rubbishy trees, unworthy of an ordinary spinney. It would not require the skill of "Capability" Brown to make improvements here, and our advice to the authorities is that the surroundings of this really noble gateway should be made worthy of Hampton Court.

We wonder what Mr. T. H. Mawson, who has had such great experience in the planning and restoring of gardens, would advise, not only with respect to this "Wilderness," but also to the several other alterations contemplated? The Office of Works would allay public fears by consulting him.

Coloured Plate.—When tropical climbers were as interesting to gardeners as New Zealand Veronicas and Chinese Primulas are now, Dipladenias were among the élite. Difficult to manage though they were, ambitious gardeners grew Dipladenias and exhibited them as balloon-trained specimens among their collections of six, or twelve, or twenty-four stove plants in flower. There are very few gardens in which D. Brearleyana, D. amabilis and D. hybrida, all, be it noted, hybrids of artificial origin, are known, much less grown to-day. One species which was greatly favoured was D. Harrisii, "most appropriately named in honour of Lord Harris, the late able Governor of Trinidad," as Sir William Hooker stated when describing the plant in the *Botanical Magazine* in 1855 (t. 4825), Messrs. Veitch having introduced it from Trinidad and flowered it for the first time in Europe in September, 1854. Unfortunately, this plant is not a Dipladenia, nor is it a native of Trinidad! Bentham had described it fourteen years earlier under the name of Odontadenia speciosa, from material collected in British Guiana by Schomburgk. The good behaviour of the plant is thus accounted for; gardeners were at a loss to understand its wonderful growth, which extended along rafters, clung round pillars and flowered with all the profusion of a Bignonia, whilst other Dipladenias required a great deal of attention. There is hope for the Odontadenia now, seeing it is removed from bad company. Under its correct name it should find equal favour with the Allamandas, with which it has much in common. Our plate was prepared by Mr. Waltham from a plant at Kew, where it grows rampantly and flowers profusely in summer in a tropical house, its long shoots hanging from pillars and wires, and its handsome rich green leaves, some of them a foot or more long, providing a good foil to the flowers, which are large, handsome, fragrant, full, glossy yellow, the tube tinged externally with red, and streaked and blotched inside with the orange colour. The largest flowers are about four inches across. If Messrs. Veitch had raised a hybrid between a Dipladenia and an Allamanda and called it Dipladenia Harrisii, the name would have stood, and we should all have been satisfied that the plant was a happy combination of the best qualities of these two genera. Possibly Nature did effect such a cross in British Guiana.

Rainfall in the United Kingdom in 1918.—Under the Defence of the Realm Act it was an offence to publish observations or records of the weather in the United Kingdom in 1918, consequently many interesting data regarding rainfall and sunshine were, perforce, excluded from the pages of *The Gardeners' Chronicle*. Now that prohibition in this connection has been removed we give the following interesting weather records sent by readers. The total rainfall in Stracan House Gardens, Kildare, was 33.50 inches; there were 199 wet days, and the greatest fall in 24 hours—of .81 inch—occurred on September 15. At Eglinton Castle Gardens, Ayrshire, there were 190 wet days, and a total rainfall of 45.45 inches, the greatest fall in one day being 1.42 inch, on January 19. The record at Greenhill Gardens, Warminster, was 140 wet days, a total fall of 37.52 inches, and the greatest fall, 1.48, on September 29; on January 5, 1.24 inch of rain was recorded, 1.18 inch on July 11, and the wettest month was September, with a rainfall of 7.25 inches. Mr. JAMES B. ALLAN, Tirley Castle Gardens, Tarporley, writes: "Few gardeners regretted the passing of the year 1918. It was a fruitless, sunless, cold, wet year. The hottest days were on May 21 and August 21, when the thermometer registered 83 deg. in the shade, and the coldest day was January 8, when there were 17 deg. of frost. After the latter date the thermometer rarely fell to freezing-point. The heaviest rainfall occurred on May 22 and July 12, when .91 inch fell on each day. On May 22 a severe thunderstorm came from the east and south-west at 3.30 p.m., and continued with great severity till 4 a.m.; much damage was done to stock and property in the neighbourhood. March was the driest month, with only nine rainy days, and a fall of .98 inch. September was the wettest month, with 5.35 inches of rain. There were 209 rainy days, and the total rainfall for the year was 31.39 inches."

Gift of a Park as a War Memorial.—At a recent meeting of the inhabitants of Markinch, Fifeshire, to consider the question of a war memorial it was announced by Provost Dixon, who presided, that it was his intention to present a public park to the burgh.

FIG. 37.—HAMPTON COURT, MIDDLESEX, SHOWING THE LONG HERBACEOUS BORDER AND DECORATIVE BEDS. [*Photograph by E. J. Wallis.*

Civilian Gardeners' War Work.—Although no one has had time during the war to attempt to obtain statistics of the amount of food produce raised by gardeners in private establishments, it is evident that the sum total has been very great. Valuable work has been done in small, as well as in large establishments, and we give the following record as an example. During the two years 1916-18 there were supplied from the garden of MR. FERGUSON, at The Hollies, Weybridge, Walton, and given to hospitals, the following quantities of vegetables and fruit:—Cabbage, Cauliflower and Kale, over 5,600 heads; Spinach and Lettuce and Greens, over 6,000 lbs.; Turnips, Carrots, Beetroot, Parsnips, Artichokes, over 4,000 lbs.; Marrows and Cucumbers, 590 lbs.; Peas, 5½ bushels; and Beans, over 1,500 lbs.; together with about 2 tons of fruit. The gardener, Mr. F. SMITH, who was responsible for this work, estimates the gross market value of this produce at over £260. In addition to this work, Mr. SMITH undertook the supervision of 2 acres of allotments, supplied over 55,000 plants to allotment holders, ran a wasp competition which resulted in the destruction of 960 queen wasps, and a Cabbage butterfly competition, which accounted for 6,751 butterflies. When it is remembered that this is but one of many thousands of examples which might be given, it will be agreed that the gardeners of Great Britain have deserved well of their country.

Profits on Bee Candy for a Gardening Charity. — The Board of Agriculture and Fisheries have received from Messrs. JAMES PASCALL, LIMITED, a cheque for £175 1s. 6d., representing the profits made by them on the sale of bee candy for the period from July 14, 1917, to June 30, 1918, in accordance with their promise to devote the whole of their profits made from this source to any charity the Board might name. The Board have sent the cheque to the Gardeners' Royal Benevolent Institution, who have undertaken to devote it to the relief of a necessitous gardener or gardeners, giving preference to those gardeners who have had connection with bee-keeping. Messrs. PASCALL have also sent the Board a copy of the trading accounts prepared by their auditors in connection with this transaction. These accounts show that the cost of the sugar represents about 80 per cent. of the price of the candy (sevenpence per pound), the cost of making the candy 10 per cent (one penny per pound), and the net profit 2 per cent. (about three-fifths of a farthing per pound). The remaining 8 per cent. represents cost of packing, postage, printing, etc.

Potato Statistics.—The March issue of the *Journal of the Board of Agriculture* will contain an illustrated supplement dealing with the cultivation, composition and diseases of the Potato, including a full report on the experiments in connection with Wart Disease, and the results of the spraying campaign conducted during the summer of 1918. Copies, price 6d., post free, may be obtained from the Secretary, Board of Agriculture and Fisheries, 3, St. James's Square, London, S.W.1.

THE SELECTION AND PROPAGATION OF PARADISE STOCKS.

(*Concluded from p.* 83.)

RAISING STOCKS FROM CUTTINGS.

In the present circumstances it may be worth adding a few details as to other possible methods of increasing the country's available supply of stocks. Until the current year we have only tried these methods in limited experiments, but it is quite clear that the freer-rooting types, such as Broad-leaved, Improved Doucin, and Nonsuch, root nearly 100 per cent. from cuttings. On the contrary, very little success has attended these experiments in the case of such types as the Doucin. We have usually taken stem cuttings of the current year's growth, but well ripened. The cuttings are made as soon after leaf fall as practical, they are each some 7 or 8 inches long, with only about two or three buds above ground level. Cuttings inserted last winter by this method will be admirable for grafting in the coming March. They have a well-developed root system, and my only criticism is that they are not ideally straight for working. I should have been more advised to plant them slightly deeper in order to get the new growth well above the ground level, or else a little shallower to allow room to put the scion on the old wood below the new shoot. So far I have not yet found much appreciable advantage in retaining a heel of old wood upon such cuttings, though possibly one might have slightly better success by so doing in the case of the Doucin. We have not tried "green wood" cuttings taken in late summer as yet, but we are under the impression that in cases such as the Doucin, which is slow to form a "callus," this might be a more certain method.

We have also tried root cuttings of the various types, and again find that the same types come quite readily, and produce a workable stock for grafting in the March of the following year. It is a method worth resorting to in these times of dearth. We have used small root cuttings about 4 inches long and about the thickness of an average lead pencil. Very early in the year we have dibbled these in, in a prepared bed, just below ground level, and when the shoots appear we have grubbed out all but the strongest. In all cases the Doucin gave us most trouble and often disappointment.

At the present time there is one type of Paradise stock, Type 3, possibly the Dutch Doucin, which might gain an unjustifiable popularity; it roots exceedingly easily by all methods, and individual stocks are very ready to "spawn." In fact, I know of folk who pulled off the "spawn" from around the collar of this type and planted them as stocks. This stock certainly does not thrive for long in our climate, though it is unfortunately a frequent visitor from abroad. It is probably to be classed among the more dwarfing types, and it is certainly one of the most unhealthy.

FIG. 38.—THE SUNK GARDEN AT HAMPTON COURT.
(*See p.* 98.)

After six years' handling and observation of the various types, it is possible for us at East Malling to say something of the individual characteristics of each member of the series from the tree-raiser's point of view. It may therefore be worth pending a few notes upon the quality of the various stocks, the order of their bud breaking, the quickness of their "callusing," and then root characters.

Type I.—Broad-leaved English Paradise.—Roots very readily from layers and cuttings, vigorous and healthy, produces stock of good quality for working, little feathered, medium season, quick to callus.

Unobtainable from abroad.

Type II.—Doucin (commonly English Paradise).—Roots only fairly readily from layers, mostly towards base, poorly from cuttings, vigorous and very healthy, produces stocks somewhat coarser than Type I., often feathered, medium season and early in leaf fall, somewhat slow to callus.

The most commonly used stock, both here and abroad, for bush Apples.

Type III.—Possibly Dutch Doucin. Our "Hollyleaf" variety, roots very readily from layers and cuttings, soon deteriorates in vigour. Often mildewed and scabbed, produces many small stocks. Medium season, quick to callus.

A very frequent rogue, especially from abroad. We are not circulating this type.

Type IV.—Probably Malus pumila. Roots fairly readily from layers, mostly at base, moderate vigour, distinctly dwarf, healthy generally, produces stock on small side for working, rarely feathered, early in season, slow to callus.

A common stock from Holland and Germany.

Type V.—Improved Doucin. (Amélioré).—Roots very readily from layers and cuttings, moderate vigour, undoubtedly dwarfing, healthy, Produces even stock of nice quality, little feathered, medium season, moderately quick to callus.

Largely used abroad for dwarfing stocks.

Type VI.—Nonsuch Paradise.—Roots very readily from layers and cuttings, very vigorous and healthy, produces stock often somewhat coarse and feathered, late in retaining leaf, quick to callus.

Unobtainable from abroad at present; most commonly used in England after Type II.

Type VII.—Unidentified, though distinct and worthy of note. Roots only fairly readily from layers and cuttings, most at base, vigorous and healthy, produces stock of nice quality and little feathered, medium season, and quick to callus.

Somewhat akin to Doucin in rooting habit, but more desirable for working purposes.

Seems to be only an English Stock.

Type VIII.—French Paradise.—Roots somewhat shyly from layers, moderate vigour, soon deteriorating, undoubtedly dwarfing, often mildewed, scabbed and cankered. Produces small stock, little feathered. Very early season, somewhat slow to callus.

Not much used in this country purposely, though a frequent rogue amongst stocks. We are not circulating this type.

Type IX.—Jaune de Metz Paradise ("Yellow" Paradise).—Roots moderately readily from layers and cuttings, moderate vigour, healthy, apparently dwarfing, produces stock of fair quality, sometimes feathered, season medium to late, quick to callus.

Used as dwarfing stock in France and Germany. More healthy here than Type VIII.

Type X.—A stock received from Germany somewhat after the Doucin type. More vigorous but apparently not so hard wooded or healthy: we have not distributed this type.

Type XI.—Free-rooting stock, selected by us from what was apparently a collection of "Crabs"; we have not circulated this type.

Type XII.—A stock with a similar history to above but showing distinct qualities, and is capable of being raised from layers. A good quality stock, and healthy.

Type XIII.—Another stock received from Germany, shows remarkable vigour of growth, is very ready rooting, and develops strong root system. It might prove promising as a stock for standard purposes if hard wooded enough.

Type XIV.—Another stock from Germany, somewhat of the Doucin type; we have not circulated this type so far.

Type XV.—A stock with a similar history to the above and not yet circulated.

Type XVI.—Another German stock, in leaf character closely resembling the Doucin, but more ready rooting and much more vigorous. It shows distinct promise for standard purposes, though possibly not quite so strong growing as type XIII. So far it has not been raised in large enough quantities for a wide distribution.

These articles are the results of the accumulated experiences of my assistants, Messrs. J. Amos and A. W. Witt. *R. G. Hatton, Wye College Fruit Experiment Station, East Malling, Kent.*

[Mr. Hatton is Director of the Wye Fruit Experiment Station, East Malling, a branch of the South Eastern Agricultural College. The Principal of the Wye College is Mr. M. J. R. Dunstan.—Eds.]

HOME CORRESPONDENCE.

Oaks at Aldenham.—We have recently had occasion to overhaul the Aldenham collection of Oaks, and have had the satisfaction of finding that it is more complete than was anticipated. We are unable to grow such as prove tender, like Quercus suber, which does well in the West of England, nor Q. semecarpifolia from the Himalayas, nor Q. crassipes and Q. glabrescens of Mexico, but apart from these we have, counting species, hybrids, and varieties, well over 100 of the hardy members of the genus, including such rarities as Q. Fabri, Q. aliena, Q. ambigua, Q. Schneckii and Q. incana. May we avail ourselves of the hospitality of your columns to ask whether any of your readers have a young plant of any of the following Oaks, which are not represented in our collection, to spare? We should be most happy to purchase or, if preferred, would gladly send other Oaks, or specimens of other choice plant, of which we have great variety, to reciprocate for such kindness. The species we desire are: Quercus alnifolia, Q. audleyensis, Q. cinerea, Q. chrysolepis, Q. coccifera, Q. glauca, Q. heterophylla, Q. infectoria, Q. Leana, Q. lyrata, Q mongolica (true, not lanuginosa syn. mongolica), Q. Morehus, Q. obtusata. Also the varieties we similarly wish to obtain are:—Q. castaneaefolia algeriensis, Q. cerris austriaca, Q. cuspidatea variegata, Q. Ilex ballota, Q. I. crispa, Q. I. Fordii, Q. I. Genabii, Q. I. latifolia, Q. lanuginosa dissecta, Q. lucombeana cana major, Q. l. crispa, Q. l. diversifolia, Q. l. fulhamensis, Q. l. pseudosuber, Q. palustris pendula, Q. pedunculata Haas, Q sessiliflora falkenbergensis, and Q. s. muscoviensis. *Edwin Beckett, Aldenham House Gardens, Elstree, Herts.*

Rosa Moyesii (p. 77).—I have not had the same experience as "*J. B. F.*" with regard to worthless varieties of this Rose. My employer bought six plants from Messrs. James Veitch and Sons at the International Show, Chelsea, 1912. All six specimens have turned out to be true R. Moyesii. The plants here are 13 feet high, and every year since they became established they have produced a mass of bloom. I have not tried to propagate Rosa Moyesii from cuttings, but in the year 1913 I saved a few hips, and when quite ripe I sowed the seeds in a pan covered with a sheet of glass and paper and stood the pan in a cold frame. During 1914 four seedlings came up, and after they were carefully removed the pan was returned to the frame and left for a few months longer, but no more seedlings developed. It would be interesting to know if "*J. B. F.*" propagated half-ripened shoots, or waited until the autumn, when the wood is hard. *G. Barrell, Chalfont Park Gardens, Buckinghamshire.*

Killerton Gardens.—The late Sir C. T. Dyke Acland, whose death was announced on p. 90, took a keen delight in gardening, at Killerton, near Exeter. His chief interest was in trees, of which there are many choice specimens at Killerton, not only in the pleasure grounds proper, but many choice Conifers and other subjects in the park and various parts of the estate. Sir Thomas also was keenly interested in the choice collection of hardy fruit, for which the garden was famous, and he was fond of showing his visitors the well-stocked fruit room, in which apples were kept all the year round. The Pear collection included practically all the varieties cultivated in this country. A Pear tree in the kitchen garden was said to be the first plant of Pear Doyenne du Comice that was introduced to this country. When Sir Thomas succeeded to the estate some twenty years ago, the pleasure grounds were in places very much over-grown with laurel and large forest trees, the latter on ground enclosed from the park. For many years the work of clearing these away from choice specimens, and making room for the planting of other choice and rare subjects, was vigorously carried out; but one point on which he was most emphatic, was that nothing must be cut out until it had been considered from all possible view points. Would that all re-makers of gardens were equally careful. Lady Acland was also keenly interested in Killerton, and showed exquisite taste in all the new work that was undertaken, which included a new Rose garden and rockery. The pleasure grounds are especially well situated for the cultivation of choice subjects, lying, as they do, on a steep, well-drained slope, varying in aspect from S.E. to S.W. One of the most striking features of the place, as viewed from some distance, is the number of flame-shaped Cupressus which are grouped on the sloping ground, among them being fine specimens of C. torulosa, C. sempervirens, C. funebris, C. Goveniana, C. macrocarpa and C. lawsoniana. Other notable Conifers, to mention a few, include a fine example of Fitzroya patagonica, also the largest plant of Thuyopsis dolabrata in this country, interesting because it was raised from a cutting taken from the original plant introduced from Japan. Other striking features of the place are the masses of Pinus insignis, Cedrus Deodara and Quercus Ilex. Of the latter there is a planting of some 40 acres on a spur of the hill facing Porlock Bay, on the West Somerset estate of Holnicote, where the same keen interest was displayed by the owner in the upkeep of the garden, and the planting and care of choice trees and shrubs. *J. C.*

Garrya elliptica.—I am surprised to learn from Mr. E. Beckett's note (page 74) that male plants of Garrya suffer from frost at Fota. A native of California and Oregon, I do not know what is its range, either in latitude or altitude, within these States, which embrace regions of very different climatic conditions. Possibly the plants at Fota were brought from a warmer part than those which thrive here and elsewhere. The oldest specimen we have is over fifty years old, growing in the open, without the protection of a wall. It came through the great frost of 1895, when the mercury stood below zero F, without injury. We had a severe spell of frost in the second week of February of this year. I looked at this Garrya recently: the foliage was perfectly fresh and green, and the catkins still decorative, though they have lost some of the freshness they had at Christmastide. Here, of course, on the west coast, our climate in winter is milder than it is further inland; but I know of a very large and fine specimen of G. elliptica growing in the open, far from any wall, in a nursery garden at Fochabers, in Morayshire, where the winters are sometimes very severe. We tried the hybrid G. Thuretii here and found it as hardy as the other, but so inferior to it as an ornamental shrub that I discarded the plants to make room for better things. I have heard it said that the famous architects, the brothers Adam, designed the slender garlands, so characteristic of their ornamentation, from the catkins of Garrya elliptica. The resemblance is certainly very striking: but, whereas Robert Adam died in 1792, and his brother in 1794, and G. elliptica was first introduced to this country by Douglas in 1828, it is accidental. *Herbert Maxwell, Monteith.*

SOCIETIES.

ROYAL HORTICULTURE.

FEBRUARY 25.—The meeting at the London Scottish Drill Hall, Westminster, on this date, was a quite good and interesting one, and the exhibition was fairly extensive and attractive.

The Floral Committee granted three Awards of Merit and eight Medals. The Narcissus Committee gave a Cultural Commendation; the Fruit and Vegetable Committee made a provisional Award; the Orchid Committee granted one First-class Certificate, four Awards of Merit, and five Medals—evidence of the extensive and excellent display of Orchids on this occasion.

In the afternoon Capt. A. Hill gave a lecture on "The Care of Our Soldiers' Graves."

Floral Committee.

Present: Messrs. H. B. May (in the chair), E. A. Bowles, S. Morris, John Green, H. R. Darlington, W. J. Bean, G. Reuthe, W. B. Cranfield, R. C. Notcutt, R. W. Wallace, John Heal, J. W. Moorman, J. W. Blakey, H. Cowley, J. F. McLeod, J. W. Barr, Clarence Elliott, Arthur Turner, C. R. Fielder, W. Howe, C. Dixon, John Dickson, E. H. Jenkins, and Chas. E. Pearson.

AWARDS OF MERIT.

Freesia Rose Beauty.—This variety has flowers of medium size, and of a rich, deep, magenta rose colour, with a white base to the lower segment and a whitish, rose-lined throat. The colouring is effective under artificial light. Shown and raised by the Rev. JOSEPH JACOB, Whitchurch.

Freesia Merry Widow.—A very large-flowered form, free-flowering, with white tube and ground, the segments having rosy-lilac shading that is accentuated at the margins. The lower segment has a soft yellow base, and each of the three lower segments have three central rose-purple lines. Shown and raised by Rev. JOSEPH JACOB.

Primula malacoides Princess Patricia.—A handsome plant, free-flowering, graceful, and effective. The individual blooms are from ¾ to 1 in. across, and the colour is deep and bright rose with a suggestion of mauve, and with a deep orange eye. In all respects it is sturdy and free, as in other forms of Primula malacoides shown by Messrs. J. CARTER AND Co.

GROUPS.

In the group of rare Conifers shown by Mr. G. REUTHE, we notice the graceful Dacrydium cupressinum, Arctrotaxis doniana, A. selaginoides, Fitzroya patagonica, Cupressus cashmeriana, Pinus Hartwegii, Abies recurvata, Podocarpus nubigena, P. chinensis Sciadopitys verticillata, and Torreya californica — a most interesting collection. (Silver Banksian Medal.) Mr. J. R. RUSSELL's collection of stove foliage plants was greatly admired. Of special interest were the Nepenthes, Dracaena Victoria, D. Godseffiana, Nidularum princeps, the beautiful Leea amabilis, and Smilax argyrea. (Silver Flora Medal.)

The finest bit of colour in the hall was provided by a batch of Salmon King Cyclamens, very finely-flowered, in a group of Cyclamens and Carnations, staged by Messrs. STUART LOW AND Co. (Silver Flora Medal.) Some bright Daffodils and Tulips, together with Primroses, Irises and Snowdrops, shown by Mr. G. W. MILLER, gave a promise of spring. (Silver Banksian Medal.) Interesting Saxifragas, from Mr. G. G. WHITELEGGE, included S. Burseriana Gloria and the red S. Frederici-Augusta. (Bronze Banksian Medal.)

Messrs. PIPER's rock and water garden lacked something in finish, but the pans of Cyclamen Coum and C. Atkinsii, embedded in grass, were charming, because of the beauty and colour of the numerous flowers. Hamamelis and Bamboos were included in the display (Silver Banksian Medal). Messrs. J. CHEAL AND SONS had a very pleasing little exhibit of Primula denticulata, and P. d. alba, backed by a few shrubs (Bronze Banksian Medal).

A delightful little contribubtion from Messrs. HERBERT CHAPMAN was generally admired. Here were seedling Daffodils, pots of the new and early Narcissus Scoutmaster, vases of Freesias in various colours, Iris reticulata and several seedlings therefrom (Bronze Flora Medal). Hardy and greenhouse plants, Primula obconica and Cyclamens made up a large group staged by Messrs. H. B. May and Sons (Silver Flora Medal).

Narcissus and Tulip Committee.

Present: Messrs. E. A. Bowles (in the chair), Geo. Monro, jnr., H. V. Warrender, W. B. Cranfield, Peter R. Barr, W. Poupart, G. W. Leak, G. Reuthe, F. H. Chapman, C. H. Curtis (hon. sec.), and the Rev. J. Jacob.

Messrs. HERBERT CHAPMAN, LTD., staged an attractive giant Leedsii Daffodil named Scoutmaster. This is a good forcing variety and suggests its King Alfred × Minnie Hume parentage, but as shown it is not very free flowering. Two bowls of Narcsisus J. T. Bennett Poe, shown by the same firm gained a Cultural Commendation—they were charmingly decorative.

Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), Jos. Cheal, Owen Thomas, W. Bates, Ed. Beckett, N. F. Barnes, W. H. Divers, J. G. Weston, A. Bullock, W. Wilks, G. F. Tinley, A. R. Allan, W. Poupart, F. Jordan, A. W. Metcalfe, P. D. Tuckett.

Mr. C. G. A. Nix exhibited several interesting variations of the well-known Potato Edgecote Purple; and Messrs. Laxton, Bros., showed Laxton's Superb Apple, a handsome, finely-flavoured late-keeping variety which the Committee thought highly of. The trees are to be inspected, and if habit and fruitfulness are in keeping with the quality of the fruit an award may be anticipated.

Orchid Committee.

Present: Sir Harry J. Veitch (in the chair), and Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, R. A. Rolfe, William Bolton, C. J. Lucas, R. Brooman-White, Frederick J. Hanbury, W. J. Kaye, Walter Cobb, J. Charlesworth, J. E. Shill, A. McBean, W. H. Hatcher, S. W. Flory, Pantia Ralli, Chas. H. Curtis, E. R. Ashton, Stuart Low, and Gurney Wilson.

Awards.

FIRST-CLASS CERTIFICATE.

Brasso-Cattleya Princess Patricia (C. Enid × B. C. Cliftonii magnifica), from Messrs. CHARLESWORTH AND Co., Hayward's Heath. A truly noble hybrid, and a great advance on the famous B.-C. Cliftonii Magnifica, whose main features it preserves intensified to a large degree. The broad sepals and petals are light rose; the finely expanded crimped and slightly fringed labellum is Tyrian purple in front, with chrome yellow disc. The tubes and side lobes are rose-coloured.

AWARD OF MERIT.

Laelio-Cattleya Zena (L.-C. St. Gothard × C. Luegeae), from Messrs. CHARLESWORTH AND Co. A very pretty hybrid, preserving the large Cattleya form, and having specially broad sepals and petals, which are rose-colour with a slight gold flush. Lip crimped at the edges, rich purple, with gold lines from the base.

Cymbidium International (eburneo-Lowianum × Woodhamsianum), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells. A delicately-coloured hybrid, with flowers of large size, Primrose-yellow, with slight rose lines on the petals and dense chestnut-red spotting on the lip.

Laelio-Cattleya Rex (L.-C. Haroldiana × C. Tityus Rex), from Messrs. FLORY AND BLACK, Orchid Nurseries, Slough. A very showy and distinct hybrid, of large size and perfect shape. The broad sepals and crimped petals are bright rosy-mauve; the well-rounded lip is ruby-purple, with golden lines extending from the base to the yellow disc.

Cymbidium albanense McBean's variety (erythrostylum × insigne), from Messrs. J. AND A. McBEAN, Cooksbridge. As shown, this is one of the best-formed and most attractive of hybrid Cymbidiums. The spike of seventeen white flowers, slightly flushed with lilac, arranged themselves in a terminal bouquet-like form. Lip white, with numerous dotted lines of purple.

CULTURAL COMMENDATION.

To Mr. J. COLLIER, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Surrey, for a strong specimen of Cymbidium Lowio-grandiflorum with twenty-nine large flowers. It is part of the original for which Sir Geo. Holford was awarded a First-class Certificate.

GROUPS.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver-Gilt Flora Medal for an extensive group in which many beautiful Cymbidiums, Odontoglossums and Odontiodas were effectively arranged. Among the best Cymbidiums were C. Alexanderi roseum, a large form with rose flowers and light purple lines on the petals; C. Beryl var. Rajah with greenish-yellow flowers having an intensely reddish-purple band on the lip, and C. Goldflake (rosefieldiense × glebelandense var. J. Davis) with a spike of medium size bronzy-gold flowers. Among novelties were Odontoglossum Doris Orchidhurst variety (Ossulstonu × crispum) with handsomely-marked flowers; O. Euterpe (amabile × Doris) O. Nora leopardinium with large densely blotched flowers; and Odontioda Alcantara Orchidhurst variety with perfectly formed rosy-lilac flowers having blush white tips.

Messrs. CHARLESWORTH AND Co. were awarded a Silver-gilt Flora Medal for an excellent group, principally of showy hybrids, the best new forms noted being Odontoglossum Orosius (Solon × Maillardianum), O. Orestes (Dora × percultum), O. Marcus (Jasper × Harryanum), all with good distinctive features; and Odontioda Lydia (Odm. Jasper × C. Noezliana), Oda. Alcides (Lambeauiana × Royal Gem), Oda. Garnet (Oda. Keighleyense × Odm. eximium), Oda. Mena (Oda. Lambeaniana × Odm. eximium) and Oda. Valda (Odm. Louise × Oda. Coronation).

MESSRS. STUART LOW AND Co., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for a large and attractive group, specially interesting in that it embodied good examples of several of the best Phalaenopsis and other imported species now rarely seen. The hybrids were fine forms of Cattleyas, Laelio-Cattleyas and Odontoglossums. Among the Cattleyas were several white forms and the pretty white-petalled C. Percivaliana Little Gem. The remarkable Laelia anceps Roeblingiana was also shown. Messrs. J. and A. McBEAN, Cooksbridge, had a group of finely-grown Cymbidiums and Odontoglossums, one fine form of Odontoglossum Thompsonianium having purple flowers equal in size to O. crispum.

Messrs. HASSALL AND Co., Southgate, were awarded a Silver Banksian Medal for a group of Cymbidiums, finely-flowered. A very handsome Cypripedium (Beckmanni × Aeson giganteum) with very large and perfectly shaped flowers, was also included. Messrs. FLORY AND BLACK, Slough, showed Odontioda Lambeauiana var. Nellie, a distinct and showy flower, and a very brightly coloured hybrid between L.-C. Charlesworthii and Sophronitis grandiflora.

SIR JEREMIAH COLMAN, Bart., showed Odontoglossum Gatton Princess (Queen of Gatton × eximium), a finely--blotched hybrid; and Dendrobium Pink Pearl. Dr. MIGUEL LACROZE, Bryndir., Roehampton (Orchid grower, Miss Robertson), showed Laelio-Cattleya Beatrice var. Roehampton, a very fine form, with richly coloured lip. Sir MERVYN E. M. BULLER, Broomhill, Spratton, Northampton (gr. Mr. Kench) sent Cattleya Clotho splendens and C. Trianae alba Broomhill variety, a large form with clear white flowers.

EDINBURGH ALLOTMENT HOLDERS.

FEBRUARY 19.—The annual meeting of the Edinburgh Allotment Holders' Association was held in the Causewayside Institute, Edinburgh. The chair was occupied by Mr. J. Campbell. In the course of his remarks the chairman said there were about 60 people on the waiting list for allotments, and the secretary was negotiating for an additional piece of land. It was also announced that the Association would hold its annual show in the Livingstone Hall on August 31, and that a sum of £23 would be offered in prize money. The financial position was satisfactory, there being a balance of £75 in hand.

CROPS AND STOCK ON THE HOME FARM.

ARTIFICIAL MANURES.

WITH the increase of motor transport and the reduction of horses on the farm, the consequent loss of animal manure increases the difficulty of managing the land, especially in private gardens, small holdings and allotments.

In no phase of land culture is the shortage of manure more felt than in the last. The cost, too, of manure cannot be put at less than 12s. per ton by the time it is on the land, as compared with the pre-war price of 6s. Small wonder, then, if some holdings fall below their usual cropping capacity. On farms—large or small—the shortage of manure is felt, but in a lesser degree. The main cause of shortage on farms has been the Army requirements for both hay and straw; but conditions are returning to the normal again.

Artificial manures, in spite of the high prices charged, are being more employed on farms and in gardens than previously. Market gardeners and allotment holders are discovering the value of stimulative food for their crops, especially sulphate of ammonia. In no case is this more emphasised than for early Cabbages and Onions, which sometimes seems to be at a standstill owing to various causes; but sulphate of ammonia sprinkled over the plot, in two applications, with an interval of one month, at the rate of 1 cwt. per acre, will effect a marvellous change. On farms, it is the same with the Oat and Mangold crops. Among farmers there is a prejudice against the use of these quick-acting manures, as they consider the crops are forced to such an extent that all the "goodness" is taken out of the land, and in time nothing will grow.

Basic slag has lately become the chief "base" manure for all crops and soils; but many persons think that because basic slag contains a high percentage of lime it is costly, and more or less useless, on chalk soils. Basic slag is often applied to crops, especially grass, at the wrong time—*i.e.*, in March or April, instead of in November or December. I have had marvellous results on poor chalk land under grass, by the judicious use of basic slag only. The increase of grass and clover of various sorts for sheep feed has been wonderful.

By the aid, also, of farmyard manure and basic slag I had one year a good cut of hay from one portion of the Downs where but four inches of soil overlies a chalk bed.

I have no hesitation in advising the use of basic slag on chalky soil for the growth of grass. On similar soil, but of double the depth, I cannot say the results justified the application for cereals, as I saw no increase in the crop, nor did I with Turnips in other fields. In the case of Oats on which 4 cwt. of basic slag was used some months before sowing (with the Oats, Italian Rye Grass and Trefoil were sown for hay, in the year succeeding the Oats), the result was a great success; a grand crop was obtained. Basic slag for Wheat, on a light loam with a clay or a gravel subsoil, is generally a success if sown with the Wheat. Last August I saw an eleven-sack crop per acre of Victor Wheat, grown after a summer fallow by the aid of basic slag at the rate of 6 cwt. per acre. One course of the machine the length of the field was not treated with basic slag, and here the crop was so poor that, had the whole field been the same, it would not have been worth the trouble of cutting.

As a lasting manure for fruit trees or vegetable crops, basic slag applied at the rate of 4 cwt. to 6 cwt. per acre gives good results, and forms a base for the application of sulphate of ammonia or nitrate of soda. On light, sandy soils, which are naturally devoid of lime, basic slag is more valuable than superphosphate, as not being so liable to be washed deep into the soil. When finger and toe disease is prevalent in Swedes, basic slag would be more efficacious as a preventive than any other manure—especially superphosphate, which is liable to render the soil acid. *E. Molyneux, Swanmore Farm, Bishop's Waltham.*

Obituary.

William Goldring.—As our pages are being passed for press we learn with deep regret of the death, early on Wednesday, February 26, of Mr. William Goldring, one of the leading professional landscape gardeners of the day. Death occurred at his home, at Kew, after a prolonged indisposition from asthma and bronchial trouble. Mr. Goldring was born at West Dean, near Chichester, in May, 1854. In 1875 he went to the Royal Gardens, Kew, where his keen interest in hardy plants soon brought promotion, and in a short time he was placed in charge of the Herbaceous department. After four years at Kew he was appointed assistant editor of *The Garden*, and, later, became editor of *Woods and Forests*. It was during his connection with these papers that he commenced to practise landscape gardening; and so well did he succeed that in 1886 he left journalism to devote the whole of his time and energies to the art in which he eventually became a great exponent of world-wide reputation.

The transformation of a market garden area into the Exhibition grounds at Earl's Court was about the first important work he undertook, and this brought him into such prominence that a year or two later he was engaged to lay out parks and gardens in India, for the Gaekwar and the Government of Baroda. This extensive work compelled him to spend the winter months in India for several successive years. Having a wide and intimate knowledge of trees, shrubs and herbaceous plants, and their development, as well as possessing imagination and the artistic perception, Mr. Goldring was able to create garden pictures of great beauty and interest. His work will long survive him. From an appreciation published in the *Kew Guild Journal*, at a time when he was president of the Kew Guild, we gather that Mr. Goldring "helped to beautify the surroundings of such stately homes as Welbeck, Hatfield, Beaudesert, Cobham Hall, Stratton, Hackwood, Knowsley, and Beaufort Castle. In France his chief work has been for Baron Rothschild, at Laversine, the Château Vermont, and at La Touquet. He has laid out or re-modelled public parks at Sheffield, Eastbourne, Weymouth, Dorchester, Norwich, Reading and Dublin. At Dublin he was retained by Government in 1903, to advise upon the re-planting of Phœnix Park, after the great gale. In 1904, at the St. Louis Exhibition, he prepared a design for a garden in the style of the late Stuart Period, surrounding the British Pavilion. For this he was awarded a Gold Medal.

A widow and two daughters mourn the loss of one who was at his best in the home. Many outside the home circle will join in sympathy with those so sadly bereaved, and, with their own regrets for the loss of one who was a most charming companion, a clever gardener, and a kindly, genial man.

James Adams.—Horticulture in Sussex has sustained a severe loss by the death of Mr. James Adams, who died at the Victoria Hospital, Lewes, Sussex, on Wednesday, February 19, in his sixty-third year. The late Mr. Adams had been associated with horticulture all his life. He was a most successful exhibitor of Carnations and ferns at various shows, including those of the Royal Horticultural Society and at Brighton. He was an old member of the Lewes and District Horticultural Society, and the valuable advice he was able to give at its meetings was always greatly appreciated. During the past ten years Mr. Adams had successfully managed Leighside Nurseries, Lewes.

T. Pride.—We record with regret the death, on February 16, of Mr. Tom Pride, a prominent South of Scotland amateur gardener, and for a number of years secretary of the Canonbie Horticultural Society. Mr. Pride, who was for the past twenty years headmaster of Canonbie Public School, was keenly interested in gardening and did much to serve the interests of horticulture in his own and other districts.

Thomas Sibbald.—The death occurred at Bishop Auckland, on February 21, of Mr. Thomas Sibbald, proprietor of a local nursery and seed firm. After holding responsible positions in London for 20 years, mainly with the firm of Messrs. James Veitch and Son, Mr. Sibbald returned in 1894 to Bishop Auckland to assist his father, and, on the death of the latter in 1899, succeeded to the business, which was established as far back as 1804.

NOTES FROM IRELAND.

BY command of His Majesty the King, the Royal Horticultural Society of Ireland, now in its ninetieth year, will henceforth take the title of Royal Horticultural and Arboricultural Society of Ireland. The extension of title is due to the keen interest taken in the Society by the President, the Marquis of Headfort, on whose initiative a Committee of Arboriculture was instituted as a sub-committee of the Council.

Representatives of the Irish Committee of Arboriculture, and of the Irish Forestry Society, have been invited to meet the newly constituted Interim Forestry Authority in Ireland on the 13th inst.

By kind permission of Viscount Iveagh, K.P., the spring show of the Royal Horticultural and Arboricultural Society of Ireland will be held in the glass covered-in yard of his lordship's Dublin residence, St. Stephen's Green, on April 10. Schedules may be had from the Secretary, 5, Molesworth Street, Dublin.

The Irish Gardeners' Association, which has its headquarters in Dublin, has good reason for self-congratulation at the result of its efforts in appealing to the Lord Mayor of Dublin for increased remuneration of the gardeners generally, and members of the society in particular, engaged in public horticultural and arboricultural work in and about the city. The corporation foreman gardener, Mr. Keegan, who is a member of the Irish Gardeners' Association, has had his salary raised to £4 10s. per week, whilst the standard wages of working gardeners are fixed at not less than £3 3s. per week.

Silver-leaf badly attacked several fine, vigorous peach trees under glass in the gardens of St. Helen's, Booterstown, Co. Dublin, a few years ago. Mr. J. Allely, the head gardener, was advised to try the formula of a local chemist who had been interested in the matter. The recipe is 1 oz. carbonate of copper dissolved in 1 pint of liquid ammonia, the solution being sprayed on the trees at the rate of one small wineglassful to one gallon of water. The specific effected a complete cure. *K., Dublin.*

TRADE NOTES.

IT is announced that under the new import regulations the United States will allow importation, under permit from Great Britain as one of the countries which maintain plant inspection, of Lily bulbs, Lily of the Valley, Narcissus, Hyacinths, Tulips, and Crocuses: stocks, cuttings, scions, and buds, or fruits for propagation; Rose stocks for propagation, including Manetti, multiflora, Brier Rose, and Rosa rugosa; nuts, including palm seeds for propagation; and seeds of fruit, forest, ornamental, and shade trees, seeds of deciduous and evergreen ornamental shrubs, and seeds of hardy perennial plants.

It is stated that the general purpose of the statute and new regulations is to prevent the introduction of certain injurious insects, various diseases, and other evils which afflict plant life, rather than to restrict normal commercial operations.

MESSRS. W. W. JOHNSON, LTD., BOSTON, South Lincolnshire, have, during the past month, despatched several thousand pounds' worth of seeds to Vladivostock, via Kobe. In pre-war days most of the seeds required in Russia were supplied by Germany. This large order is but the nucleus of a much larger consignment that will, before many months have passed, be despatched to far-away Siberia.

MARKETS.

COVENT GARDEN, February 26.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of thé samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.

Heather, white, per doz. bun.	6 0–10 0	— yellow, per doz. blooms	5 0– 6 0
Lilac, white, per bunch, 6's ...	3 6– 4 0	Violets, single, per doz., bun. ...	6 0–10 0

REMARKS.—The conditions this morning are similar to those given last week. All white flowers are very scarce and prices are much higher, especially for white blooms. A return of milder weather no doubt will alter the situation during the next few days. Consignments from France which suffered so much through the severe weather last week arrive in a much better condition. White Narcissus appear to be finishing but is gradually being replaced by small quantities of white Stocks; prices should be more normal before the end of this week. The supplies from the Channel Islands have also been checked by the sharp weather; only two small consignments reached the market last week. There was practically a famine in foliage throughout last week, especially in Asparagus plumosus, A. Sprengeri and Maidenhair Fern, as much as 3s. 6d. per bunch being asked for the Fern.

— Barcelona, per cwt. ...	110 0 —	Pineapples, each	5 0–10 0

REMARKS.—English black Grapes continue in fair supply for the season of year. A consignment of about 160 packages of black and Muscat Grapes from Belgium reached the market this week, and it is anticipated that there will be further arrivals but the quantity will be limited. Pears (Californian) arrived in larger quantities packed in cases and half cases. A consignment of Teneriffe Tomatos is due this week. All supplies of forced vegetables are very limited with the exception of Seakale which is more plentiful. Outdoor vegetables are not so plentiful owing to the recent hard weather. E. H. R.

ANSWERS TO CORRESPONDENTS.

FAILURE WITH LILIUM CANDIDUM: *F. W.* From your description of the behaviour of the plants, it is quite possible that the flowers were affected with the fungus Botrytis, which forms a greyish-black mould on the petals. The leaves also are affected, and the fungus is first noticed in the form of buff or rust-coloured spots or blotches on the buds and foliage. We do not think the failure is due to wrong cultivation, as this Lily succeeds in full sunshine as well as in semi-shaded situations. Care should be taken to see that the soil is well drained and fairly rich. If you will forward specimens in the flowering season we shall be pleased to examine them, as we shall then be in a better position to state the true cause of failure.

GARDEN TRUCKS: *H. T. (B.E.F.).* The garden trucks you describe can, we believe, be obtained from Messrs. W. Wood and Son, Ltd., North British Wharf, Wood Green, London, N. 22.

GRAFTING WAX: *J. W.* Mastic Lhomme-Lefort could possibly be obtained from M. Tissot, 7, Rue de Louvre, Paris, or M. Truffaut, 90. bis. Avenue de Paris, Versailles. There are other French "cold" grafting waxes, *e.g.*, Mastic Français and M. Normand. English-made waxes (cold) may be obtained from horticultural sundriesmen.

GRUBS IN FERN ROOTS: *P. J. P.* The insects attacking the roots of your Adiantum Ferns are weevils. Both the adult insects and the larvæ which you send are very destructive pests and difficult to exterminate. The adult weevils feed at night and hide by day so that they are difficult to detect. They may be caught at night by bringing a lighted lamp into the plant house and catching them as they drop from the plants. If white paper is spread beneath the pots the insects will be detected the more easily. The larvæ may be trapped by placing pieces of such vegetables as Potatos and Carrots in their haunts. They may also be destroyed by carbon-bisulphide. Make holes in the soil with a piece of stout wire and pour about a tea-spoonful of the chemical in two or three of the holes in each pot.

LANDSCAPE GARDENING: *V. R.* The "ordinary gardener" has much to learn before he can feel even fairly equipped to practise as a landscape gardener. The subjects in which he must be proficient include land surveying, drawing and mensuration. If he is a young man probably his best course would be to obtain a few seasons' work under a first-rate landscape foreman. He would then obtain the necessary practical experience in groundwork, which includes the making of new gardens and also the alterations of existing pleasure grounds. Surveying and levelling are of great importance, and proficiency in these may generally be obtained by arrangement with a local surveyor, who would probably also be willing to give tuition in measuring quantities and estimating the value of work done. Drawing, both free hand and geometric, including scale drawing, are also essential and for these instruction can be obtained at science and art classes in most towns. The ability to make a fair analysis of soils, so as to ascertain their suitability or otherwise for the trees, shrubs and plants which he wishes to employ in the planting scheme, is also necessary. We are not acquainted with any school of landscape gardening, so the would-be practitioner must rely to a great extent on private study, and practise assiduously in plan drawing, in which absolute accuracy is essential. Besides an intimate knowledge of his craft he must possess a broad general knowledge and be able to express himself clearly and fluently. The best text books on landscape gardening are those by Repton, Kemp, and T. H. Mawson; *Formal Gardens*, by Reginald Blomfield, would also be useful.

NAMES OF PLANTS: *J. C. S.* 1, Gaultheria Shallon; 2, Olearia dentata; 3, Pieris floribunda; 4, Pernettya mucronata.

SALT FOR ASPARAGUS: *Bourne End.* Salt is a stimulant for Asparagus, applied at the rate of from 4 to 6 lbs. per square rod. Salt is especially useful to Asparagus growing in light soils and should be applied in April. Much harm would be done by a too liberal use of salt; an overdose, especially in the case of heavy soils, would act most injuriously on the plants, and not a few failures with Asparagus may be traced to its indiscriminate use.

WASTE CARBIDE OF CALCIUM: *W. P.* Spent carbide of calcium from the generator of an acetylene plant may be used on the soil with good effect, although it is not so valuable as slaked lime. It should be placed in a vacant corner and allowed to become nearly dry, when it may be dug into vacant land. No planting should be done until at least two months after the application of the material. A correspondent in *Gard. Chron.*, October 5, 1916, recommended its application at the rate of one barrowful to every 12 square feet of ground. He states that he found it effective in destroying soil insect pests, including wireworm.

SEEDS FOR BRITISH COLUMBIA: *J. W. T.* Write to the Agent-General for British Columbia, 1, Regent Street, London, S.W.1.

SCUTELLUM IN MAIZE AND WHEAT: *G. H. H. W.* *Questions:* (1) A generally accepted opinion that the scutellum in the Maize and Wheat is the true cotyledon? (2) Is the ferment secreted in the scutellum or in the adjacent tissue of the endosperm? (3) What is the function of the epidermal layer of the scutellum? (4) Do the cells of the scutellum multiply after germination? *Replies:* (1) It is a widely held view that the scutellum represents the single cotyledon in the grain of grasses, but this view is not accepted by all botanists. (2) The ferment is secreted by the scutellum. (3) The function of the epidermal layer appears to be the secretion of ferments and the absorption of the material so made soluble. (4) In all probability the cells of the scutellum do not multiply after germination.

SPRING OPERATIONS IN THE ROCK GARDEN: *N. K. W.* If the weather is open in March, worn-out groups of plants may be lifted and replanted, at the same time renewing or enriching the soil. Groups of plants which have grown too thick and crowded for the place they occupy may be lifted and fresh portions, sufficient to furnish the space and allow room for development, planted. April is the best time for putting out young plants which have been wintered in frames. The weather then is usually more showery, and the plants commence to grow freely at once. In addition, there is always much trimming and tidying to be done in the rock garden, cutting the dead portions of plants away, and top-dressing plants that have grown out, with gritty soil. Weeds also begin to assert themselves, and should be kept under. Heaths are usually trimmed over after flowering, but should not be cut back hard. Hydrangea paniculata is usually cut hard back, leaving only two or three buds to form the new flowering branches. If the Spiræa you refer to is Spiræa japonica, all last year's growths that flowered should be cut back to buds showing at the base.

THE CELEBRATED XL ALL SPECIALITIES. BEEN ON TOP FOR 25 YEARS AND STILL THERE!—XL ALL CAUSTIC WINTER WASH (in powder). 1lb. tin makes 8 to 12 gallons. It thoroughly cleanses Fruit Trees and Bushes, both buds and bark. Can be used any time before the buds begin to swell in the spring. XL ALL NICOTINE LIQUID INSECTICIDE. The gardeners' favourite Wash for the absolute destruction of Thrip, Scale, Mealy Bug, &c. If this wash is used occasionally, a total absence of insects, both on Fruit Trees and Plants can be secured in any garden. XL ALL NICOTINE SHREDS. The most potent, safe, and effectual Fumigant. Used without any apparatus; simply burn on the floor of the Greenhouse. XL NICOTINE FUMIGATING COMPOUND. Both in liquid and cake, these old favourites are still as popular as ever. Many other XL ALL Preparations are indispensable in the garden. Get a complete list from your N.S. or Florist, or send to me for one and name address of your nearest Agent.—G. H. RICHARDS, Manufacturer, 234, Borough High Street, London, S.E.1.

ON THE WALLED GARDEN.

WRITTEN between June, 1392 and September, 1394, for the help and comfort of a young wife, *Le Ménagier de Paris** is an interesting account in manuscript which gives a picture of the domestic life of a Parisian home during the period which four and a half centuries of dusty oblivion have failed to dim† and contains quaint references to horticulture as practised more than 500 years ago.

The identity of the author of this manuscript and his history are unknown. But his book makes plain that he was no longer a youth when Charles V came to the throne in 1364; that he was a burgher of Paris; and that he ordinarily dwelt there, though in the habit of making journeys to distant parts of the kingdom and to Flanders. The same source points to his association with the administration of the city, to his practical acquaintance with judicial terms, and with the etiquette imposed by legal tradition.

The author himself describes the circumstances which gave rise to his book. Verging on old age, he had married a girl of fifteen, of better birth than himself, orphaned and from a different province. Shortly after their marriage, she begged him not to take her to task publicly for her "*décontenances et simplesse*," but to reserve his correction until they were alone together. To this he agreed joyfully but, reflecting that it would be more in accordance with their love for each other did he anticipate such reproof by instruction, he set himself to devise a general treatise on the duties and circumstances of a wife. It was natural that his counsels should be almost paternal in character. Aware, moreover, that she must outlive him, he dwells on the difference in their ages and tells her with a certain tender delicacy that he writes for "*son mari qui sera*." He divides his treatise into three sections. The first consists of religious and moral precepts, which, having regard for the youth of his wife, he illustrates from the histories of Griselda and of Melibee and Prudence, and from other romances of the day. In the second section he instructs her in the care and upkeep of her house and servants and of her garden, and in the thirds treats of games and other indoor amusements, and of the science of hawking. The prologue reveals the writer's solicitude for his wife's happiness. "Know," he says "that I am not displeased but glad that you care for your Roses and Violets, that you should trim hats and dance and sing amidst our friends and equals. Nevertheless, I do not desire to see you at the feasts of Lords and Ladies since such would be unsuitable for people of our estate." The following is a translation of his notes "On the Walled Garden"‡:—

Sow, plant or graft in damp weather, in the evening or early morning, before the heat of the day, and when the moon is waning; and water the stalk and the earth but never the leaf.

Likewise, never water in the heat of the sun, but in the evening or early morning; neither cut Cabbages, Parsley nor other green stuffs which shoot, because the heat of the sun will scorch the cut and burn it and thus the plant will not break again at the place where it has been cut.

Note that rainy weather makes good planting but bad sowing, because the grain clings to the rake.

All Saints' Day brings Broad Bean planting, but so that these may not be frozen, plant towards Christmas, in January and February and in the beginning of March so that should some be frozen others may not be. When the plants show above ground, harrow them and break the first shoot; and so soon as they have six leaves scatter earth upon them. The earliest are always the best and should be eaten the same day as they are shelled, otherwise they become black and bitter.

To keep Marjorum and Violets through the winter cold, put them not suddenly from heat to cold, nor from damp to cold, because, if kept for a long time in a damp cellar in winter and suddenly planted in dry ground they will die. *Et sic de contrariis similibus.*

In winter strip off the dead branches of the Sage bush. Plant Sage, Lavender, Costmary, Mint, and Clary in January, February and until June; and Parsnip freely. Sow Sorrel until March and later, during the waning moon.

Note that December and January cold kills White Beet, that of it which is above ground, but in February, directly the frost ceases, the roots throw out new and tender shoots; and a fortnight later comes Spinach.

February.—Savory and Marjorum taste alike and are sown when the moon wanes and are but a week in the soil. Savory lasts only until Saint John's Day. Plant trees and vines and sow white and headed Cabbages during the waning moon. Note that bearded Runners bear in the year if they be planted bearded.

February brings Spinach; its leaves are long and indented as are Oak leaves and it grows in tufts like White Beet and should be blanched and then well cooked. Beet comes afterwards; and Strawberries and Raspberries plant well.

March.—Graft during the waning moon. Plant House Leek from March until Saint John's Day. Violets and Gilliflowers§ sow in March or plant on Saint Remy's Day.‖ Whether sown or planted, when the frost comes replant in pots during the waning moon and place under cover in a cellar or shelter from the cold. In the day time put the plants in the open air or sunshine and water at an hour when the water is soft and fair, making sure that the earth is dry before putting the pots under cover again at evensong. Plant Beans and break the first stalk with the harrow as aforesaid. Note that Parsley sown on the eve of Lady Day is above ground in nine days' time.

Plant Fennel and Marjorum in March or April when the moon wanes. Note that Marjorum requires a richer earth than do Violets, and if it has too much shade becomes yellow. When the plant has taken good hold, uproot in tufts and replant in pots, giving plenty of room. Note that branches cut, set in the earth and watered take root and grow. Note also that soil manured with cow and sheep dung is better than that manured with horse dung.

Common Violets and Armenian Violets do not require to be covered up or mulched; and note that Armenian Violets will not flower for two seasons in the same soil, but when gardeners have had them a year in the soil they sell them, and replanted elsewhere they flower.

Sow Sorrel and Basil in January and in February during the waning moon and until March. If last year's Sorrel be replanted, plant it with the earth which is round its roots. There is art in picking; gather always the big leaves, letting grow the little leaves which are above; and if the whole must be picked, cut the stalk down to the level of the soil and new shoots will come.

Sow Parsley, weed it and grub up all little stones; and that sown in August is the best, not growing too tall and keeping good the whole year.

Lettuces should be sown and note that they are not long in the ground and come up close together. On this account, thin out and so give them room to grow. Note that the French Lettuce seed is black whereas the Lettuce seed of Avignon¶ introduced by Monsieur de la Rivière,** is whiter; and these Lettuces are better and more tender than the French plants. Note that the seed is gathered from one bud after another as each bud throws its husk. Note also that Lettuces do not seed themselves and thus may be pulled up root and all when required for eating.

* Le Ménagier de Paris. Publié par Jerome Pichon pour la Société des Bibliophiles Francais, à Paris, 1846, T.2, P. 43, et seq.

† By a coincidence the three copies of the existing manuscript of *Le Ménagier de Paris*, came to light the same year (1843). Two, one a fifteenth century transcription of the other, were discovered in Paris, and the third in the Royal Library at Brussels. M. Pichon collated these manuscripts in his edition of the treatise.

‡ Courtillage in the original i.e., the production of a courtil or garden attached to a house. Stym. lat. curtis—low latin curtile.

§ Probably Gilliflower—Clove or Carnation.

‖ October 1st.

¶ Laitue romaine (Cos Lettuce), so called because Avignon was at that time the seat of the Papacy.

** Bureau de la Rivière, son of Jean de la Rivière and of Isabean d'Angeraut, married Marguerite, Dame d'Auneau, Minister and Councillor of State to Charles V and Charles VI. Bureau de la Rivière shared the fate of Jean le Mercier, Jean de Montagu and others of the "Marmousets," who were summarily disgraced in 1392, directly the madness of the King had placed the chief power in the hands of his uncles, Philippe le Hardi, duc de Bourgogne and Jean, duc de Berri. Arrested at Auneau, de la Rivière was committed to trial, but escaped with his life through the King's intervention. He died in 1409.

Pumpkins.—The pips are the seeds, and should be soaked for two days before sowing, and should not be watered, but let grow until they show above ground, when the roots and the soil around them should be moistened, but not the leaves. In April, water the seedlings gently, and plant them 4 to 6 inches deep in the ground and half a foot apart. Water the roots continuously by means of a pot with a hole, hung upon a stake, and either a straw through the hole or a piece of new cloth within the pot.

Sow Beet in March: and when ready to be eaten cut near the root, so that it may break afresh; and treat Borage and Orach in the same manner.

White Cabbage and Large-Headed Cabbage are similar. Sow during the waning moon in March: and, when the plants have five leaves, take up carefully and set half a foot one from the other, putting them in the soil up to the eye and watering the root. These are eaten in June and July. Sow ordinary Cabbage in March, and re-plant in May. Roman Cabbage is akin to ordinary Cabbage, since the seeds of both grow on the same stem: the ordinary Cabbage seed in the middle and at the top of the stalk, the Roman Cabbage seed at the bottom. The second crop of the Cabbage comes in Lent. It lasts until March; but has then a stronger savour, and on that account is best parboiled. Stalks should be pulled up from the ground at this time. Plant Cabbages in July, when it rains.

If ants abound in a garden throw Oak sawdust on their nest, and when next it rains they will either move away or die, since sawdust holds moisture.

Sow White Beet in April and May, during the whole month, for eating in June and July. Gather the Summer Beet, but leave the roots in the ground: after the winter they will break anew when scatter earth upon them, and turn over the earth near by, planting out the new shoots and gathering the old. From April until Saint Mary Magdalen's Day* is good sowing for White Beet: and Lenten Beet may be sown in July until that day, but no later, and is so called. Spinach may be treated likewise. Beet shoots, when taken out of the ground, should be re-planted in rows.†

In April and May plant out white and ordinary Cabbage sown in February and March. May brings new Beans, Turnips and Radishes. Sow Parsley on Saint John's Eve and also on the eve of Assumption Day.‡ In early August and on the Feast of the Assumption sow Hyssop, and, when the moon wanes, Cabbages for Easter eating; Parsley also, since it does not grow to an ear. Note that Beet breaks afresh five or six times like Parsley and may be cut above the core until mid-September. Thenceforth it may not be cut lest the root wither, but the outer leaves may be stripped by hand. At this time gather all Beet seeds; this is not in fear that the cold will injure them, but so that the stalks may break afresh when the seeds be gathered. Parsley must no longer be cut, but stripped.

After the Feast of the Nativity of the Blessed Virgin § plant Peonies, Lords and Ladies, Lily bulbs, Rose trees and Gooseberry bushes.

In October plant Peas and Beans 4 inches deep and 4 inches distant one from another. Use only the largest Beans, which are always fresher than those of smaller size, and plant in small quantities as each moon wanes so that frost may not destroy the whole planting.

Sow or plant pierced Peas in fine and dry weather, since if moisture penetrate the Pea will rot and so come to nothing.

Replant Cabbages until All Saints' Day: and though the leaves be eaten by caterpillars until there remain nothing but the skeleton, strip off the lower leaves and the stalk will break again if replanted to the depth of the upper eye. Let stalks wholly stripped of leaves remain in the soil and they will break of themselves. To replant in dry weather needs moistened earth. Rainy weather brings moisture enough.

If there come caterpillars in great number upon a Cabbage, when it rains scatter ashes upon them and they will die. But look also on the underside of the leaves, and if there be white mites clinging in quantities, cut off those leaves and throw them far away, for these are young caterpillars.

Sow Leeks in due season to replant in October and November.

To grow Grapes without pips, take a vine plant with roots when the February moon waxes and spit the vine stalk in two equal parts to the root, removing the core of each half. Lop the vine, bind the halves together closely with black thread, stopping up at the top with earth, and replant, manuring well.

To graft or ingraft a Cherry or Plum tree on a vine, prune the vine stalk, and in March split it four inches from the top. Remove the core, put in its place the kernel of a Cherry stone and bind up with black thread as aforesaid.

To graft or ingraft a vine on a Cherry tree, prune a vine which has been long planted close by a Cherry tree, and in March, near Lady Day, and first making a hole neither too large nor too small through the trunk of the Cherry tree, put the vine stalk through the hole and at least a foot beyond, and stop up the hole on both sides with clay and moss, wrapping the whole around with cloths against the rain. Peel the bark of the vine stalk to the green where it touches or is within the Cherry tree, thus shall the sap of the vine mix more easily with that of the Cherry. Leave both together in this wise for two years, afterwards cutting the vine stalk below where it enters the Cherry tree.

Ten or twelve different trees may be grafted upon the trunk or stem of an Oak. Thus, saw a little way into the Oak, and first cutting the graft in such a manner that the bark remains untouched on the one side of the cut, place it between the bark of the Oak and the wood, the bark to the bark and the wood to the wood, and cover the whole with clay and moss and with cloths so that neither rain nor snow nor frost may strike it.

To keep Roses through the winter, cut unopened buds with long stalks and put them, without water, in a little empty barrel, such as is commonly used to hold conserve. Fasten up the barrel tightly so that nothing may enter it, tie two heavy stones to it, one at either end, and set it in a running stream.

Gardeners say that Rosemary will not grow from seed in French soil, but that small branches stripped from the bush and planted strike easily. To send these branches a long distance, wrap them in oiled cloth, stitched, and rub over on the outside with honey, afterwards powdering with wheat flower.

Monseigneur de Berri* has been heard to say that Auvergne Cherries are bigger than French for the reason that in Auvergne the Cherry trees are layered.

Thus, so far as history is concerned, the story of the lives of these interesting persons begins and ends with a picture of the wife dancing and singing through the garden of her youth, weaving chaplets of Violets and Roses, while her husband sits writing of his knowledge of the world to guard his love from mishap, great or small. *F. M. Graves.*

FIG. 39.—GALANTHUS IMPERATI.
(See page 107.)

* July 22nd. † "Par ordre" in the original. ‡ August 15th. § September 8th.

* Jean de France, duc de Berri, third son of Jean II (1350-1364) and of Bonne d'Armagnac. He fought at Poitiers, and was one of the hostages delivered to the English by the treaty of Bretigny in 1360.

GALANTHUS IMPERATI.

THE identity of the various species of Snowdrop is often difficult to determine, but there is no doubt that what is known to gardeners as Galanthus Imperati is a very desirable plant. I believe it was this species which used to grow so well at the foot of the famous wall in Canon Ellacombe's garden at Bitton, and no one who saw it thriving there would be content not to possess it. I have not had an opportunity of looking up the original description, but the name Imperati suggests an Italian origin, and it may well be that this Snowdrop is merely the Italian representative of our well-known G. nivalis. That it is a plant of southern origin may perhaps also be inferred from the treatment under which it seems to thrive, for it certainly seems to like a more sheltered spot, and can stand more roasting in summer than the common Snowdrop. G. Imperati resembles G. nivalis in having a pale green, horse-shoe mark on each of the inner segments, and its flowers are nearly twice the size of those of the latter species. If there is any difference, apart from size, between the two species, it is that the foliage of G. Imperati is relatively shorter and less developed when the flowers open in January. *W. R. Dykes, Charterhouse, Godalming.*

THE ROSARY.

BLACK SPOT AND ROSE JULIET.

THE article on "A New Discovery Concerning Black Spot Disease," by *Wild Rose*, in your issue of January 4 of this year, is of distinct interest to me, as I have had this vexatious fungus disease under general observation for some time past. Even after the perusal of this article I am doubtful whether we have yet wholly fathomed its subtleties. Like the observer, Mr. Alcock, quoted by *Wild Rose*, I also noticed a winter ago pustules on the current year's shoots of Roses affected in the previous autumn by black spot. Thinking these would be fructifications of this fungus, I confirmed my opinion by microscopic examination.

In my limited experience of modern Roses the variety Juliet is by far the most addicted to black spot, the Lyon Rose perhaps coming next: but the disease does not make much headway with this variety until well into August, whereas Juliet begins to spot early in July, with the result that the disease may interfere with the perfecting of its first blooms. For three years I have had a plant of this variety under observation. With the exception of Juliet and to some extent the Lyon Rose, black spot has not caused me much trouble: but I have found the disease in late autumn developing on Rose bushes adjacent to Juliet, *e.g.*, a plant of Hugh Dickson growing quite close became somewhat badly spotted in 1917. The bush of Juliet was moved and isolated. Last autumn the Roses that had been her associates, including the above-mentioned Hugh Dickson, kept free from black spot, showing that Juliet was the source of infection.

During the late spring and early summer of 1917, this bush of Juliet was repeatedly sprayed with a standard solution of potassium sulphide and soft soap; black spot, however, began to appear as usual on the leaves in early July. For a time I removed the leaflets as soon as they showed the least sign of infection, thinking this might check or stop the spread of the disease: but it pursued its accustomed upward course with no apparent diminution, the shoots becoming defoliated in early autumn.

When the plant was isolated, all shoots made the previous summer were cut away to the old wood, thus removing the pustules which apparently carry the disease over the winter. Further, this drastically pruned plant was well drenched with potassium sulphide solution. It produced last summer three rather spindly, long shoots. The leaves of these became as badly affected with black spot as ever. The disease followed its usual course, attacking the leaves successfully from the base upwards, and leaving the stems bare of foliage and rotted with pustules by the early autumn. Flower buds terminated two of these shoots, but these never managed to develop into passable blooms. It is far from my intention to imply that I have made an exhaustive attempt to prevent or control this disease, but the above experiments would seem to show what a difficult fungus pest it is to cope with, especially in respect to the variety Juliet. Others who have tried this variety have the same complaint against it, and threaten to banish it from their gardens. Personally, I should be sorry to see this Rose disappear. It is a variety that has been much abused, aesthetically speaking, but it has some well marked merits as a bloom, *e.g.*, unusual colouring, good size, fragrance, and a stiff stalk well clad with foliage right up to the flower. A single good bloom of Juliet furnishes a vase without the addition of extra foliage. Further, this variety, if the disease will allow, is a strong grower; and, a point not always recognised, its foliage is Briar scented. It is also a cool season Rose, withstanding wet, an additional merit in its favour. Turning to its defects, apart from its proneness to black spot, one might mention the frequency with which the flower comes double-centred and the failure at times to show a sufficiency of gold in its petals—a defect that may be due to over much sunshine and atmospheric dryness. As compared with H.T. Roses generally, it lacks freedom of blooming, but its merits outweigh its defects. Is there no easy and satisfactory method of coping with black spot on Juliet? If not, I fear this Rose is doomed soon to become only a memory. *J. P., Carlisle.*

BERBERIS AGGREGATA.

One of the best of the new species of Barberries introduced from China, more especially in regard to the beauty of its fruits, is Berberis aggregata.* This species was originally collected by Potanin in the province of Kansu, but was first introduced to cultivation by Mr. E. H. Wilson. He collected it in Western Szechuan in 1908 and again in 1910, and plants raised from seeds sent home by him are becoming widely distributed in gardens. It is a deciduous shrub of bushy, rather erect, but not ungraceful habit; its shoots armed with slender three-pronged spines ½ to ¾ inch long.

FIG. 40. FRUITING BRANCH OF BERBERIS AGGREGATA.

The leaves are dullish green, oval to obovate in outline, ½ to 1¼ inch long, sometimes entire, but usually armed with a few small teeth. The flowers are yellow, and borne in short racemes, followed by dense clusters of salmon-red globose fruits very densely packed on the twigs. They are ripe in October, and give the shrub a very handsome appearance at that season. The plant is hardy, grows well in soil of even moderate richness, and its fruits set fertile seeds which provide a ready means of obtaining an abundant supply of young plants. The Barberry sent out by Messrs. J. Veitch and Sons as B. Geraldii, and also known as B. Prattii, is now regarded by Dr. Schneider as a variety of B. aggregata. *B.*

* Berberis aggregata, Schneider in Bull. Herb. Boissier, sér. 2, vol. viii, p. 203.

POTATO FACTS AND FALLACIES.

Potatos seem to be booming again! What surprises one is that so many varieties reputedly not immune to Wart Disease, should still be offered for the current year's planting when there are more than enough super-excellent varieties to choose from which are immune. Surely no gardener would be so foolish as to introduce any but immune sorts into his garden, however tempted farmers may be to do the contrary.

The discussion as to the relative values of uncut and cut seed is just a renewal of what has happened over and over again in the past, as a search through the early volumes of *The Gardeners' Chronicle* will amply prove, some preferring the one and some the other method.

I consider there is not much difference. What appears to be a weak eye in a large tuber may be so in appearance only and not in fact, so much depending on the rooting medium in which the primary roots grow. This can be demonstrated by starting the seed tubers slowly in boxes, using a compost of equal parts of loam and leaf-mould with a sprinkling of superphosphate of lime added, and keeping the cut portion with different classes of eyes apart. It will be seen to resolve itself into a question of time for the weak to become as robust as the strong. I had a very striking instance of this fact two years ago, when from one source I had Eclipse in small seed and from another quite large Potatos which were cut rather close, and no difference whatever was observable in the crop. The same year I had 1 cwt. of another variety, the seed of which was so small that I hesitated to plant that variety at all and did not take the trouble to sprout the tubers previous to planting. These were slow in growing at the commencement, and the shoots appeared above ground in the most erratic manner. Finally, they proved successful and certainly I have never seen a stronger haulm than they produced, with a good crop and grown without any manure. Is it really essential, or even important, to lime newly-cut Potatos? The custom is very old, but I have never been convinced of its utility. Probably soils may influence the keeping qualities and *vice versa* of cut seed. Yet, if it be considered that a started growth is in a position to strike root immediately into the soil subsequent to the planting of the tuber, it will be apparent that the chance of the parent rotting before the roots had got a grip of the soil is not great, if likely.

There is another fallacy about the growth of the Potato that is so common that I noticed it was repeated by an "expert" in a paper last year; growers were warned to beware when working the soil in summer lest in doing so the roots of the Potatos should be damaged, the effect of which it was remarked would be a shortage of the crop owing to young tubers being destroyed. Now it is clear that the Potato being stoloniferous and the stolons proceeding from the stems, though they may or may not also produce a few roots, that the cutting of the extreme points of the true roots can, judging from analogy, do no harm, but rather be advantageous. Late earthing, however, would be harmful, and in no one respect can it be beneficial.

The practice of confining the growth of the Potato, for table use, to one or at most two stems, is good, because it is the only way by which tubers of the best quality can be produced, at the same time allowing each plant an abundance of space. It is remarkable that of all garden vegetables we find the Potato most frequently overcrowded and always with bad effects. Then there is the somewhat cognate question as to the best time to plant. As to early varieties there is no question of doubt. But some are of opinion that late varieties should not be planted till late in the spring, assuming, as they do, that early planting weakens the growth. My experience does not lead me to recognise that this is true. Late planting and late maturity go together, occasionally too late for maturity at all and I could not wish for growth to be stronger than that from late varieties planted as soon as the soil is fit to receive them in spring. And this is confirmed by observation. Last year the farmers in East Lothian who planted early, lifted the crop in good time and in good quality. The late planter, on the other hand, waited till almost winter before lifting and then was glad to get rid of his crop at the earliest moment to save himself from loss through abnormal shrinkage and bad keeping. *R. P. B.*

THE ALPINE GARDEN.

CODONOPSIS.

The genus Codonopsis includes some 20 or more species distributed over Northern Asia, the Himalayas and China. They are members of the Campanula family, and nearly all are characterised by having a most unpleasant odour when bruised. C. ovata, illustrated in Fig. 41, known also in gardens as Glosocomia clematidea, is a native of the Himalaya, being found in Kashmir at an elevation of from 10,000 ft. to 13,000 ft. It is said to grow wild in stony soil in grassy places with a northern exposure, so that it apparently prefers a shady situation. It is a hardy perennial forming quite a tuberous or woody rootstock, from which are produced tufts of mostly unbranched stems clothed with glaucous green leaves. The pendant, bell-shaped flowers are of a slaty blue colour, veined and speckled with white and yellow, and are borne on the ends of shoots one foot to two feet tall. The beauty of the flower is inside the drooping bell, and this fact should be borne in mind when selecting a position in which to plant. The most suitable situation is on a raised portion of the rock garden, in deep, well-drained sandy loam.

[Photograph by W. Irving.

Fig. 41.—Codonopsis ovata: flowers blue.

Other members of the genus in cultivation include the beautiful, blue, Burmese C. convolvulacea with open, Clematis-like flowers, illustrated in Fig. 42. The deep lavender-blue flowers are about 3 inches across. The plant is a perennial, and only one stem is produced annually from the woody rootstock C. rotundifolia from the Western Himalaya has blue flowers veined with yellow on trailing stems. C. Meleagris is a recent introduction from China, sent home by Mr. Forrest when collecting for Messrs. Bees, Ltd. The plant is of nearly erect habit, with broad leaves, and stems about 9 inches high, each terminating with a drooping bell-shaped flower. The blooms are of a pale porcelain-blue colour, with reticulations of chocolate purple and a green base. As in C. ovata, the beauty of the flower is inside the bell. *W. I.*

THE MARKET FRUIT GARDEN.

February did not do much to help forward work in the open, already greatly in arrears. The first half of the month gave us the most severe weather experienced during the winter. There was snow on the ground at the opening, and frosts were recorded on the first fourteen days; the thermometer needle fell lowest on the night of the 7th, when 13 deg. of frost were registered. This cold spell was welcome as a check to vegetation, which was in a forward state, but it put a stop to work on the land and prevented winter spraying from being started, owing to the barrels required for the work being full of ice. As soon as the thaw set in there was a return to rainy conditions, the total rainfall for the month being 2.70 in. on 11 days, which is over the average. Thus it was not until the end of the month that ploughing, digging and planting could be resumed and spraying begun. It is to be hoped that the finer weather of the closing week of February will continue, for it has been a very trying winter. The absence of sunshine has been most depressing, whilst for weeks we have practically marked time with regard to work. It has frequently been a case of finding make-shift jobs to keep the men employed, whilst no progress could be made with work that badly needed doing.

Power Spraying.

For winter spraying the new power sprayer, described in recent notes, was brought out for the first time. It worked smoothly from the start, and I am much pleased with the experience. Spraying used to be hateful to all concerned, but the work is robbed of half its terrors now that an oil engine does the pumping and there are no heavy knapsacks to carry about over rough ground. The saving of time and labour is, however, of greater importance. I find that three men, two to spray and one to look after the engine and keep the tank supplied with solution, get through just about double the work that five used to manage with pneumatic, knapsack sprayers, whilst the work is more thoroughly done. The machine could easily supply four nozzles, which would effect a still greater saving of time; but at present it is arranged for only two, owing to scarcity of labour and the high price of hoses and other fittings. Knapsack sprayers do excellent work where the trees are not too big and the area is small, but they are too slow for economical

use on a large scale. So much time is wasted in carrying back and refilling the empty knapsacks, whereas a power plant delivers the spray continuously, the only halts being for shifting the main pipe and drawing the engine along the headland at long intervals. With wages at their present level it is necessary for growers to make use of labour-saving appliances.

INCREASE OF ENEMIES.

The possession of an efficient spraying outfit is a great satisfaction to me, because I feel that success in fruit-growing depends more and more upon one's power to deal with pests and diseases. Certainly, these enemies have increased in number and virulence in recent years. Old gardeners testify that the culture of fruit used not to be half such a struggle as it is to-day. The reason is probably to be found in the extension of the industry and closer methods of planting. Where thousands of trees of one species are growing close together, as they are in market plantations, pests and diseases have every opportunity to spread. We have an example of this in the Raspberry growing district of Blairgowrie, in Scotland. Mr. J. Hodge, writing in the *Scottish Journal of Agriculture*, says that the great crops which rejoiced the hearts of the growers, and made the industry in its early days a kind of goldmine, are only a memory now. The depredations of insect pests have become so serious as to threaten the very existence of the plantations, and the yield of fruit has been gradually decreasing since 1909 until it has reached a level that would hardly be profitable if markets were normal.

FILLING GAPS.

One job completed during February was the planting of odd trees all over the farm to fill gaps caused by the grubbing out of trees that had failed for one reason or another, notably Plums affected with Silver Leaf. Every year many trees have to be purchased for this purpose. It is not work than can be done with much satisfaction, because the new trees seldom grow really well. This is not to be wondered at, since they have to be planted in exactly the same spot as the old trees, and so in soil drained of the plant foods required; and they are generally overshadowed by their larger neighbours. It is a different matter when several rows are grubbed up, because the trees are worn out or unsatisfactory. Then the ground can be well manured, deeply ploughed, and a crop of Potatos grown, so that it gets a year's rest from fruit production and a thorough cultivation. After this young trees can be planted with good prospect of success, and there is nothing to deprive them of light and air. When filling gaps the holes should be dug wide and plenty of manure introduced. I spread the manure after the roots have been just covered with soil, and then complete the filling in.

PARADISE STOCKS.

It is to be hoped that the investigations carried out at the experimental station of the South Eastern Agricultural College (see pp. 71, 82, 100) will go far to clear up the present confusion amongst dwarfing stocks used in propagating Apple trees. Market growers have generally been advised to plant bush trees on English Broad-leaved Paradise, but it must have been obvious to many of them that they did not receive what they ordered. The lack of uniformity often seen in the growth of trees of one variety, all supposed to be on the same stock, is ample evidence of this. A mere glance at the roots of young trees received from the nursery is sometimes sufficient. I have recently planted trees from five different nurseries. All are supposed to be on English Paradise, but it is quite evident, from the variation in root system, that the different nurserymen have not used the same dwarfing stocks. This is no longer surprising when we learn from these experiments that the foreign nurseries, from which most of the stocks used in this country are obtained, do not produce a single stock of two of the most desirable types of Paradise, *i.e.* the Broad-leaved and the Monarch, whilst the stocks they send us (mostly Doucin) pass under various names. Most of the trees planted on this farm have been propagated on the place; but I could never feel sure that the stocks brought in were true to name. Results certainly indicate the contrary in many cases. There are trees of the same variety on supposed English Paradise, Doucin and Crab growing in the same blocks, sometimes in the same row, and no difference in size or habit traceable to the stock can be detected in many instances. *Market Grower.*

NOTES FROM AMERICA.

STEVIA SERRATA.

I HAVE often wondered why Stevia serrata via. has never become popular in England as a winter cut flower. In America it is grown in immense quantities, and proves invaluable in the cut flower markets in winter. It may be had in flower as early as November 15, and by giving the plants cool treatment they may be kept in fine condition until the end of February. The plant closely resembles a small Eupatorium in flower and foliage, and forms densely cymose heads of white flowers in wonderful profusion. Their light and graceful appearance render them specially valuable in all kinds of floral work, and no florist here who does a retail business can afford to be without them. The flowers will stand shipment to long distances and keep fresh in water for a number of days. The cultural requirements of the plant are very simple. Here cuttings are taken from cut back plants in February or March, they root within ten to fourteen days in an ordinary propagating bench and are then potted singly. The bulk of growers plant their Stevias about the end of May in ground which is only moderately rich, as the plant is a rampant grower. The shoots are pinched as required until August 1, when the plants are lifted carefully and potted. Shading is necessary for a few days after potting until the roots become re-established. Before frost arrives the plants are placed in a cold frame or greenhouse. Very cool treatment produces the best sprays of flowers, but the temperature should not fall below 32° at any time.

In England I think culture in pots through the summer and plunging the plants in coal ashes would be the best treatment. Some growers prefer this plan even here. An abundant water supply and applications of liquid manure are necessary, as are top dressings of Clays' Fertiliser, which, by the way, has a large sale amongst practical gardeners in this country. Some years ago I forwarded

(*See page* 108.)

seeds of this plant to Messrs. James Veitch and Sons, and specimens were shown at one of the R.H.S. shows at Vincent Square. I am sure any enterprising market grower would find the culture of this plant profitable. There are both dwarf and tall forms of Stevia. While most of the growers here favour the dwarf type, the tall produces much longer and more handsome sprays. A variegated variety is used for bedding. When pinched frequently this plant makes a useful subject for carpeting.

CHRISTMAS TRADE IN PLANTS.
